

## INTERNATIONAL APPLICATION PUBLISHED UNDER THE PATENT COOPERATION TREATY (PCT)

<b>(51) International Patent Classification <sup>6</sup> :</b> <b>G06F 3/00, 3/033, 3/023, G09B 21/00, A61F 4/00</b>	<b>A1</b>	<b>(11) International Publication Number:</b> <b>WO 96/30822</b> <b>(43) International Publication Date:</b> 3 October 1996 (03.10.96)
<b>(21) International Application Number:</b> PCT/US95/03591 <b>(22) International Filing Date:</b> 27 March 1995 (27.03.95) <b>(71)(72) Applicant and Inventor:</b> FOREST, Donald, K. [US/US]; 209 Croydon Avenue, Rockville, MD 20850 (US).		<b>(81) Designated States:</b> AM, AT, AU, BB, BG, BR, BY, CA, CH, CN, CZ, DE, DK, ES, FI, GB, GE, HU, JP, KE, KG, KP, KR, KZ, LK, LT, LU, LV, MD, MG, MN, MW, MX, NL, NO, NZ, PL, PT, RO, RU, SD, SE, SG, SI, SK, TJ, TT, UA, UG, US, UZ, VN, ARIPO patent (KE, MW, SD, SZ, UG), European patent (AT, BE, CH, DE, DK, ES, FR, GB, GR, IE, IT, LU, MC, NL, PT, SE), OAPI patent (BF, BJ, CF, CG, CI, CM, GA, GN, ML, MR, NE, SN, TD, TG).  <b>Published</b> <i>With international search report.</i>

**(54) Title:** METHOD OF AND APPARATUS FOR DATA ENTRY**(57) Abstract**

The apparatus and method of the invention relate to data entry in ideographic languages, including Chinese, Japanese and Korean, and to interactive displays and interactive display methods for use by persons temporarily or permanently lacking normal motor capabilities. In a preferred embodiment, each option of a menu is associated respectively with a selectable region (3606), (3610), etc.) displayed adjacent an edge of a display (2112), forming a perimeter menu and leaving a region (3680) in the center of the perimeter menu for the output of an application program. Selectable regions may be on the display, outside the display, or both. A menu option may be selected by clicking on the associated selectable region, by dwelling on it for a selection threshold period or by a cursor path toward the selectable region, or by a combination thereof. Remaining dwell time required to select a selectable region is preferably indicated by the brightness of the selectable region. Submenus of a perimeter menu may also be perimeter menus and the location of a submenu option may be foretold by the appearance of its parent menu option. Menu options may be ideographs sharing a sound, a structure or another characteristic. Ideographs, which may be homophones of one another, may be associated with colored indicating regions and selection of an ideograph may be made by speaking the name of the associated color.

## Method of and Apparatus for Data Entry

## Technical Field

5 The present invention relates generally to interactive display terminals and interactive display methods, and more to interactive display terminals and interactive display methods for use by persons temporarily or permanently lacking normal motor capabilities. It also relates to systems and methods for the assessment of the motor capabilities of persons lacking normal motor capabilities. It further relates to interactive display terminals and interactive display methods for  
10 use in speech synthesis for persons having impaired speech. It also relates to systems and methods for the control of devices, including appliances, by persons lacking normal motor capabilities. It further relates to interactive display terminals and interactive display methods for selecting one menu option from a menu. It further relates to systems and methods utilizing sound recognition for selecting a menu option from a menu. It further relates to data and order entry systems including,  
15 and data and order entry methods utilizing, an interactive display terminal. It also relates to interactive display terminals and interactive display methods for displaying and selecting ideographic characters, such as are used in the Chinese, Japanese and Korean languages. It also relates to interactive display terminals and interactive display methods for producing an indication of progress toward and/or away from selection of a menu option.

## Background Art

Many persons suffer from various neurogenic muscular disorders, such as Cerebral Palsy ("CP"),  
30 Traumatic Brain Injury, Spinal Cord Injury, Muscular Dystrophy, Amyotrophic Lateral Sclerosis and Multiple Sclerosis. These conditions can result in a reduced ability to voluntarily control or prevent the movement of parts of the body, including the head, limbs and digits, muscle stiffness, weakness, limited range of motion, abnormal posture, involuntary muscle tremors, involuntary muscle activity causing involuntary motion, impaired ability to voluntarily stop motion, impaired

ability to coordinate muscle activity, and/or impaired ability to sense the position of a part of the body. Any one of these symptoms may impair an affected individual's fine motor control.

Moreover, while some individuals affected by a neuromuscular disorder may be able to exercise fine motor control with enormous effort, the struggle to do so often fatigues the individual, limiting the period of time the individual is capable or comfortable performing the fine motor control task.

Neuromuscular disorders are often systemic in effect, impairing an individual's ability to operate prosthetic devices, such as a wheelchair, and to perform the activities of daily life, such as speaking, walking and operating household appliances. Speech is frequently affected since the mechanics of producing speech require coordination of many muscle groups -- the muscles of the diaphragm which push air over the vocal cords, the muscles of the larynx, jaws, tongue and lips. The inability to use or coordinate these muscle groups may result in impaired speech. Depending upon the degree of impairment, speech may be totally absent, present but impaired to the point of unintelligibility, or intelligible on the whole but with occasional unintelligible words. The ability to walk is often affected since walking requires coordination and voluntary control of many muscle groups. Furthermore, impaired fine motor control may prevent or impede an individuals from effectively operating household appliances or computer input devices.

Devices are available which produce speech, control appliances and facilitate computer access for some persons having neuromuscular disorders ("NMD operators"). Devices which produce speech for individuals whose own speech is impaired, called Augmentative and Alternative Communication ("AAC") devices, allow the operator to select words or phrases by spelling the words, by specifying an abbreviation for the phrase or by selecting a sequence of symbols, and then speak the selected words or phrases using an electronic speech synthesizer. However, due to the systemic nature of neuromuscular disorders, NMD operators are often unable to efficiently use a standard keyboard and mouse. For example, an NMD operator who is unable to stop the movement of a limb with precision, when attempting to use a keyboard or mouse, may move his arm toward the target key or move the cursor toward the target object on the display but overshoot the target. If he has involuntary tremors and cannot hold a limb still, then, when attempting to use a keyboard, he may hit keys adjacent to his target key. If he has involuntary motion moving left to right, then, when attempting to use a keyboard, he may have difficulty accessing an intended key on the right side of the keyboard.

The benefits of interfacing an NMD operator to a general purpose computer so that he may control

the computer and devices attached to it ("computer access") are both numerous, because many of the problems faced by the disabled are susceptible to a computer-driven solution, and profound, because of the psychological deprivation occasioned by a severe physical disability. The benefits potentially obtained through computer access for individuals affected by neuromuscular disorders include:

- a. Speech synthesis. A computer connected to a speech synthesizer enables an NMD operator with impaired speech to direct the computer to speak for him.
- b. Device control. A user who is physically unable to operate a household appliance, for example, a television, video cassette recorder, compact disc player, radio, alarm clock, telephone, light, thermostat, dimmer or power switch, may be able to control the appliance via a computer equipped with an interface he can control.
- c. Access to general purpose computer applications. NMD operators may make use of the same general purpose computer application programs ("applications") as able-bodied users, including applications for word processing, database, computer-aided instruction, access to literature accessible via computer, spreadsheet, time management and computer utilities.
- d. Enhanced self-esteem and peer approval. Adolescents with CP are obviously different from their peers. They are often surrounded by non-normative assistive technology, e.g. wheelchair or walker, special school bus equipped with a chair lift, stair lift, standing aid, AAC device, feeding apparatus, bath seat, toileting apparatus, etc. In addition, they may drool, lacking the ability to coordinate lip closure with swallowing. Nonetheless they are adolescents and need peer approval to support them in their maturation from dependent children to independent adults. Today, demonstrated facility with a computer is an emblem of intelligence among adolescents, so computer use provides adolescents the opportunity to prove their intelligence and thus potentially rewards NMD operators with both self-esteem and peer approval.
- e. Privacy. Some severely disabled school-aged children require nearly constant physical assistance to transfer them to and from bed, to feed them, help them with toileting and personal hygiene, etc. Because they are constantly attended, all their mistakes in class or when doing homework are known to their attendant, often a family member. They do not have the opportunity to make mistakes in private. Computer use, if it can be done without assistance, affords the NMD operator the opportunity to avoid the embarrassment of showing their failings to their attendant.
- f. Expanded personal interaction. Some severely disabled individuals, e.g. quadriplegics, are essentially incarcerated by their disability. They interact with their family or their caretakers,

depending upon whether they live at home or in an institution. Their circle of friends is often very small. Using a computer and a modem, they can expand their circle of friends to include the tens of thousands of people who periodically connect to worldwide electronic networks to trade information on topics of mutual interest. Moreover, the interaction via present computer networks is mostly textual; there is no voice or visual interaction between users. Since messages are customarily composed and read off-line to minimize connect time charges, no one even knows how long it took the sender to enter the text. Electronic networks thus afford the disabled user an opportunity to relate to others on an equal footing, not as a disabled person to his able-bodied peers, something many NMD operators dearly want to do but were never able to.

NMD operators vary widely in their motor capabilities. Even individuals having the same medical diagnosis may require completely different technologies for computer access. Many NMD operators are able to use an oversize keyboard, a device having a pressure-sensitive surface divided into squares, each square associated with a letter of the alphabet. The squares may be sized to match the operator's abilities, but typically each square is two inches on either side. NMD operators who are unable to efficiently use an oversize keyboard may use another conventional computer access solution, called an "on-screen keyboard", which, as illustrated in Figure 1, is a picture of keyboard drawn on a computer display (1101). The operator selects a letter by pointing to that letter's key image on the display with a pointing device ("pointer"), then indicating that he has reached his target either by operating a switch, a process called selection by click, or by maintaining the location indicated by the pointer ("dwelling") on the key image for a predetermined period of time (the "selection threshold"), a process called selection by dwell. Switch operation includes, but is not limited to, each of the following: opening the switch, closing the switch, opening the switch multiple times within a predetermined period, and closing the switch multiple times within a predetermined period. A program executing on the computer determines which letter the operator has selected and processes the letter or passes it to some other application program which processes the letter as if it came from a true keyboard.

Conventional pointing devices include a mouse, trackball, joystick (which may be integrated into a keyboard, e.g. TrackPoint II®), stylus and graphics tablet, lightpen, thumb wheel, touch screen, touch panel, head pointer, oculometer, intraoral pointer and eye tracker. They may be active, e.g. a lightpen that emits an infrared beam, or passive, e.g. an eye tracker that uses images of an individual's eyes to determine where his eyes are focusing. Conventional switches include a button

on the mouse, a switch in the tip of the stylus actuated by pressure or the release of pressure, a switch mounted on the user's wheelchair operated by a turn of the head to or the switch below a keyboard key.

5 Dwell time may be continuous or discontinuous depending upon the operator's motor capabilities. In continuous dwelling, if the operator moves the cursor from one key image to another region of the display, the time accumulated on the key image is discarded so that if the operator returns to that key image he must dwell on it for the full selection threshold to select it. Discontinuous dwelling, by contrast, compensates for involuntary tremors which pull the operator off the desired  
10 key image. Accumulated dwell time on a key image is remembered, so that on return to a key image, the operator need only dwell for a period equal to the difference between the selection threshold and the previously accumulated dwell time for that key image. Accumulated dwell time is reset to zero for all key images following the selection of any one key image. Conventional on-screen keyboards do not indicate to the operator the dwell time associated with any key image.

15 There may be a single selection threshold period for all key images or each key image may be associated with its own selection threshold period. In the latter case, keys associated with shorter selection threshold periods are easier to select than keys associated with longer selection threshold periods.

20 As was mentioned earlier, computer access permits an NMD operator to run a variety of applications. One such application is speech synthesis. In a computer-based speech synthesis system, a computer system displaying an on-screen keyboard is connected to a speech synthesizer.. The operator spells the desired word or words using the on-screen keyboard. These are then  
25 spoken by the speech synthesizer. Another application of the on-screen keyboard is word processing. Figure 2 illustrates an example of a combined display of an on-screen keyboard and a word processing application program. The on-screen keyboard (0201) is shown on the lower portion of a display connected to a computer system (not shown) which also executes the word processing application program whose output (0203) appears on the upper portion of the display.  
30 Letters selected by the operator are input to the word processing application program.

Due to impaired fine motor control, many NMD operators have difficulty selecting a key image by click or by dwell and this difficulty increases as the size of the key image decreases. Figure 1 shows an on-screen keyboard containing 81 total keys including 26 alphabetic keys, 10 numeric

keys, 12 function keys, 4 arrow keys and 29 special purpose keys. Drawing this many key images on a display restricts the size of each key image making each very difficult for many NMD operators to select.

5 When a display is shared between application program output (0203) and an on-screen keyboard (0201), as is the display shown in Figure 2, the size of each key image must be reduced from its size in Figure 1 to allow space for the application program output. Thus, as more display space is allotted to application program output, the key images become more difficult for an NMD operator to select.

10

Many NMD operators have difficulty using the conventional dwell selectable on-screen keyboard because they cannot maintain a steady pointer position. The body member with which they control the pointer may move slightly ("drift") when they want it to remain still. One approach to this problem is a variation of the on-screen keyboard, depicted in Figures 3, 4 and 5 and called a  
15 quaternary on-screen keyboard ("quaternary keyboard"). The quaternary keyboard provides for larger key images. The alphabet is divided into four groups of letters, each displayed in one of the four quadrants (1302), (1304), (1306) and (1308) of the display, as shown in Figure 3. The operator selects one of the four groups by, for example, pointing to and dwelling on one quadrant of the display. The selected group is then exploded into four subgroups, each displayed in one  
20 quadrant of the display, as shown in Figure 4. Once more the operator selects one of the four. The selected group is exploded into four letters and each letter displayed in one quadrant of the display, as shown in Figure 5. The operator again selects one of the four. This letter is then input to an application program (not shown).

25 The quaternary keyboard illustrates the use of a menu hierarchy in computer access. Each of the four groups of letters (1302), (1304), (1306) and (1308) is a menu option. Each of these menu options is itself a menu which includes other menu options. A menu hierarchy exists if at least one of a menu's menu options is itself a menu. Hereinafter, a menu accessed from another menu may be called a submenu, and the options of the submenu may be called submenu options. If a menu  
30 hierarchy is narrow and deep, many selections are required to make the desired choice. If a menu hierarchy is broad and shallow, each layer is composed of many menu options.

The quaternary keyboard greatly expands the size of a single key image and thus accommodates certain NMD operators with drift or involuntary tremors. The cost of this adjustment is high

Instead of selecting a letter with one pointing motion and dwelling for one selection threshold, the quaternary keyboard requires three pointing motions and dwelling for three selection thresholds. Thus the operator's productivity is dramatically reduced from the standard on-screen keyboard depicted in Figure 1.

5

The computer access advantage gained from the quaternary keyboard is greatest when the quaternary keyboard occupies the entire display. In this configuration the size of each of the four active display regions is maximized, making them easier to hit and dwell on for the operator. However, this configuration allows no room on the display for the output of the application program being run by the operator, the reason he is sitting at the computer in the first place. This does not prevent the on-screen keyboard from passing letters to the application program since an application program need not be visible to be active, but it does prevent the operator from seeing what the application program has to show him. The more of the application program output that is displayed, the smaller the on-screen keyboard, the smaller each active region of the on-screen keyboard and the more difficult access becomes. Figure 6 illustrates a display combining a quaternary keyboard and output from two application programs.

10

15

20

25

Another conventional structure for selecting of a menu option from a menu is a pie menu. A pie menu is an opaque region on a display divided into selectable slices, each slice associated with a menu option. The pie menu suffers some of the drawbacks discussed above, particularly that, while displayed the pie menu occupies more space than a linear menu and obscures much of the output of the operator's application program. For illustrations and a discussion of pie menus, see Callahan, Jack et. al., "An Empirical Comparison of Pie vs. Linear Menus", Computer Science Technical Report Series, TR-1919, University of Maryland, September 1987.

30

NMD operators who cannot effectively use a conventional keyboard or a pointing device may use a computer access method called "joystick patterns". Figure 7 depicts a conventional joystick pattern device. The device (1602) is connected to a joystick and to a computer. The operator pushes the joystick to the top, bottom, left, right, top left corner, top right corner, lower left corner or lower right corner, closing one of eight switch contacts within the joystick housing. That switch position is then indicated on the display (1604). A sequence of consecutive of switch closures encodes a letter or other programmed output that the device (1602) displays on an LCD display (1606) and sends to the connected computer, simulating keyboard input.

The conventional joystick pattern device is ill-suited for many NMD operators. The involuntary tremors common some neuromuscular disorders may result in unintended switch closures. In addition, the device does not provide an indication that the operator is moving a body member in an unintended direction until switch closure occurs. For example, an operator with CP who intends to move the joystick the right but actually moves it to the upper right receives no indication from the device, prior to switch closure, that he's not on target. Moreover, the device requires that the operator memorize the encoding of each letter or other output since there's no indication on the display (1606) which sequence encodes which letter. Further, the device provides no support for head pointing, although the head is often the best controlled part of an NMD operator's body.

10

NMD operators who cannot effectively use either a conventional keyboard or a pointing device but can reliably actuate a switch may use a computer access method called "scanning", which is subdivided by cursor control technique into three types of scanning: automatic, directed and step. In automatic scanning all the operators' options, for example, the letters of the alphabet, appear on either a static or dynamic display (depending upon the implementation), organized in rows and columns. At the scanning interval, usually about one second, a cursor moves from one row to the next. When the cursor indicates the row containing the letter the operator wants, he closes a switch. The machine now moves the cursor from one letter to the next within the selected row until the operator closes the switch again. The operator has now selected one letter. In directed scanning, like automatic scanning, the cursor moves at the frequency determined by the scanning interval, however, it moves only when the switch is closed. To select an option, such as a row or a letter in a row, the operator opens the switch while the cursor indicates the desired option. In step scanning, the cursor moves with each switch activation.

15

20

As one can well imagine, writing a sentence via any of these scanning techniques is an extremely slow process, since selecting a single letter may take many seconds.

25

Problems of computer access cascade and affect the quality of verbal interactions between AAC device operators ("AAC operators") and others. People speak much faster than they type. Not surprisingly, operators who speak with AAC devices, particularly NMD operators whose motor deficits impair their ability to use a keyboard, lag substantially in their conversations. The slow pace of an AAC operator's word production disrupts normal verbal interaction. Speaking persons, accustomed or not to the AAC operator's slow rate, often lose patience in conversations with AAC operators. They may prematurely terminate the conversation, read the AAC device display in an

30

attempt to guess at the AAC operator's intended utterance and so accelerate the interaction, lead the AAC operator, ask predominantly yes/no questions, change the topic of conversation with little input from the AAC operator and otherwise dominate the interaction. The AAC operator often has difficulty participating as an equal partner in the conversation. He may be unable to change the topic, interject a humorous comment in a timely fashion or respond to a question before the speaking person changes the topic. Slow AAC operators may be perceived as mentally slow. Thus the quality of verbal interactions where one party uses an AAC device to speak depends significantly upon the AAC operator's rate of word production.

Increasing an operator's letter or menu option selection rate proportionately increases his word production rate and increases the operator's productivity in data entry generally. Letter or menu option selection time includes the time the operator requires (a) to comprehend the menu options displayed, (b) to move the pointer to the desired menu option on the display, and, in selection by dwell, (c) the selection threshold period, or, in selection by click, (c) the time required to operate the switch. Decreasing any one of these increases the operator's productivity, assuming all other steps in the selection process are unaffected.

Personal interactions are composed of more than speech alone. People in conversation gesture to one another, use facial expressions, change the object of their gaze and make non-speech utterances (e.g. "hmmm-mmmm") to bid for a turn to speak, to grant such a bid made by the other party, to request to continue speaking and to acknowledge, accept or dispute what has been said. Ideally, the production of speech from an AAC devices does not distract the AAC operator from the personal interaction and subject matter of the conversation. This is possible if the operator habituates the AAC device access technique and menu structure, producing speech without focusing on each step of the process, much as automobile drivers habituate mechanical tasks, such as changing gears and switching between foot pedals, and focus their attention on pedestrians or traffic lights while operating their vehicle.

Another consequence of personal interaction during conversation for an AAC device operator is that the operator needs a way to easily enable and disable the AAC device operator interface so that movement the operator makes during personal interaction, for example, nodding his head, is not interpreted by the AAC device.

As noted previously, neurogenic muscular disorders may impair the ability of an individual to

sense the position of a body member. An NMD operator thus relies more than his able-bodied peer on the location of a cursor or similar automated indication of body member position. Conventional access methods which use a pointer do not provide additional feedback to the operator of the position of a body member.

5

Access methods which require the NMD operator to make the same movement for most selections, such as single switch access, mouth sticking (the use of a small rod held in the mouth and used to depress keys on a keyboard) and head sticking (the use of a rod mounted on the head and used to depress keys on a keyboard), may result in repetitive motion injury, particularly after years of use.

10

There are several aspects of the invention, each addressing one or more of the problems described above and/or one or more problems specifically addressed by that aspect of the invention. The objects, disclosure and description of each aspect is separately described below under one of the headings: (A) Perimeter Menu, (B) Confinement, (C) Dwell, (D) Path Directness, (E) Intersection, (F) Alignment, (G) Length Order, (H) Location Indication, (I) Sound Match, and (J) Ideographic Languages,. Where there is background art applicable to an aspect in addition to that described above, the additional background art is described below.

15

#### A & B. Perimeter Menu and Confinement

20

One object of the invention is to facilitate computer access by a disabled operator.

A further object of the invention is to facilitate menu selection by an operator having impaired ability to maintain a body member in a steady position.

25

Another object of the invention is to facilitate menu selection by an operator having impaired ability to stop motion.

Yet another object of the invention is to simultaneously display an application program window and a computer access menu which does not obstruct the application program window.

30

Another object of the invention is to allow an operator to enable and disable a menu.

A still further object of the invention is to synthesize speech for an operator having impaired

speech and impaired fine motor control.

Still another object of the invention is to facilitate device control for a disabled operator.

5 Another object of the invention is to reduce the cognitive demand of speech synthesis for the disabled.

A still further object of the invention is to enlarge the effective area of a selectable region without concomitantly reducing the area available for information display.

10

Another object of the invention is to speed data entry.

Yet another object of the invention is to facilitate computer access for an operator having impaired ability to sense the position of a body member used for computer access.

15

#### C. Dwell

Conventional systems allowing selection by dwell do not provide an indication to the operator of either how much dwell time has been accumulated for any selectable region or how much more  
20 dwell time is required to select a selectable region. Consequently, an operator of a conventional system who is dwelling on a intended selectable region has no indication, other than his estimation from prior use of the system, that he has nearly made his selection and can plan his next movement to the next selectable region or that he has very nearly made his selection and can begin moving to the next selectable region. Furthermore, an operator of a conventional system who is dwelling on  
25 an unintended selectable region, has no indication, other than his estimation from prior use of the system, of how close he is to making an unintended selection and thus how important it is to act quickly. Conventional systems using discontinuous dwell give no indication of the accumulated dwell time associated with a selectable region either when the operator dwells on that region or when the operator ceases dwelling on that region. Some disabled users can dwell relatively easily  
30 on their intended targets for short periods of time, but have difficulty dwelling for long periods. If such an operator knows that only a little more dwell time is needed he may be able to satisfy the dwell time required for selection, without preparing himself to dwell for an extended period.

Conventional menu-driven data entry and order entry systems incorporating pointing at intended

selections employ a two step selection procedure. In the first step the operator indicates, with a pointer, his intended selection. The system then provides feedback, for example, by highlighting the indicated selection, showing which selection the operator has indicated. In the second step, the operator selects the indicated selection, for example, by operating a switch. Thus, conventional data entry and order entry systems are ill-suited to circumstances where the operator cannot easily operate a switch while maintaining the pointer on the intended selection.

While the two step procedure is not complicated, many operators require some training to learn it, and, if they are infrequent users of the system, these operators may require refresher training. Simplifying the procedure further would lessen the need for initial and refresher training.

One object of the invention is to facilitate the use of systems allowing selection by dwell.

Still another object of the invention is to facilitate device control by the disabled.

A further object of the invention is to increase the independence of the disabled.

Yet another object of the invention is to facilitate the use of a data entry or order entry system by an intermittent operator.

Another object of the invention is to facilitate ordering by someone seated in a vehicle.

#### D. Path Directness

The on-screen keyboard with dwell selectable key images is ill-suited for use by many NMD operators. Selection by dwell may fatigue NMD operators or may require greater fine motor control than they bring to this task. Operators with impaired ability to stop motion and those having involuntary tremors have difficulty maintaining the location indicated by a pointer on a key image for a period sufficient to distinguish intentional dwelling from unintentional dwelling. Consequently, some NMD operators who try to use on-screen keyboards often miss their target key images and/or accidentally select unintended key images. Following such an error, the operator must erase his erroneous selection by selecting the backspace or undo key. As the number of erroneous selections increases, the operator's productivity decreases markedly, since each error requires a correction in which there might be another error.

Conventional on-screen keyboards require the ability to select by dwell or by click and thus are limited to operators with these capabilities. Conventional on-screen keyboards do not utilize the relatively intact motor capabilities of some NMD operators to compensate for impaired ability to select by dwell or by click or to speed up the slow process of selecting by dwell. For example, while an NMD operator may overshoot a key image, his directional control may be relatively intact. Conventional on-screen keyboards do not exploit this capability.

The dominant computer operating system for graphic applications on general purpose computer systems today is the Windows® Operating System. Windows® assigns meaning to the cursor location. When the operator moves the cursor on top of a menu item and clicks, Windows® interprets the action as manifesting an intent to choose that menu item. The operator's path to that menu item, whether direct or circuitous, is irrelevant. Operators who can move toward a target accurately but cannot maintain the location indicated by a pointer on the target cannot effectively use standard Windows® applications through the conventional interface to these applications.

Often NMD operators cannot steady a pointer while operating a switch; the act of operating the switch triggers involuntary muscle activity pulling the cursor off target. For these operators, conventional selection by click is not practicable. Conventional selection by dwell also requires greater fine motor control than many NMD operators bring to this task. Operators with impaired ability to stop motion may overshoot their intended target. Operators whose voluntary muscle activity is accompanied by some involuntary muscle activity affecting their directional control cannot point accurately. Operators with involuntary tremors cannot maintain the location indicated by a pointer on a key image. Consequently, NMD operators who try to use on-screen keyboards often miss their target key images and accidentally select unintended key images. Following such an error, the operator must erase his erroneous selection by selecting the backspace or undo key. As the number of erroneous selections increases, the operator's productivity decreases markedly, since each error requires a correction in which there might be another error.

Measures of an individual's fine motor control assist a physician or therapist in evaluating the effectiveness of a treatment program, including assistive technology, and in gauging the severity of a disability. Such measures help the physician or therapist in determining what treatment course to pursue and whether the severity of a certain disability justifies the risk of a particular treatment option, such as neurosurgery.

One object of the invention is to facilitate selection of an option from a menu.

Another object of the invention is to indicate to an operator moving a cursor toward an option in a menu displayed by a computer system, which option the computer system believes the operator is moving toward.

Another object of the invention is to display a menu on a display so that a large contiguous area on the display is not obstructed by the menu.

Still another object of the invention is to make use, in computer access, of relatively unimpaired directional control in persons having impaired fine motor control.

A further object of the invention is to indicate to an operator moving a cursor toward a dwell-selectable option in a menu, a changed selection threshold of the dwell-selectable option.

Yet another object of the invention is to more efficiently select an option from a menu on a display.

Another object of the invention is to speed up selection of an option from a menu by an operator having impaired ability to operate a switch while the operator simultaneously keeps a cursor location within a region on a display.

Another object of the invention is to help an operator with a disability control a pointer.

Yet another object of the invention is to speed data entry by an individual with a disability.

A still further object of the invention is to facilitate artificial speech generation by a person having impaired speech due to a neurogenic muscular disorder.

Yet another object of the invention is to facilitate device control by a person having a neurogenic muscular disorder.

Another object of the invention is to measure an individual's ability to move one of the individual's body members in a direct path from a starting position to an ending position.

Yet another object of the invention is to facilitate computer access for an individual who cannot stop movement cleanly.

#### E. Intersection

5

One object of the invention is to facilitate computer access by an operator having impaired ability to maintain a body member in a steady position.

10

Another object of the invention is to facilitate the selection of a desired menu option by an operator having impaired fine motor control.

A further object of the invention is to synthesize speech for an operator having impaired speech and impaired motor control.

15

Yet another object of the invention is to use an operator's directional control in computer access.

A still further object of the invention is, in selecting a menu option from a menu of dwell-selectable menu options, to compensate for an operator's impaired ability to maintain a body member in a steady position by using the operator's relatively intact motor capability .

20

#### F. Alignment

Conventional on-screen keyboards do not compensate for NMD operators' inability to stop motion. Suppose the operator has been fitted with a head pointing device so that his head motion moves the cursor and that he's using the quaternary keyboard shown in Figures 3, 4 and 5. Assume further that, as he attempts to point to the quadrant containing the "j" key image (1308) in Figure 3, he is unable to stop on that quadrant and continues turning 20 more degrees to the left. There are two known ways of responding to this situation: (1) the cursor may continue to track the operator's motion and disappear from the display, leaving no indication to the operator of the location of the cursor and consequently causing some operator disorientation, or (2) the cursor may "stick", i.e. remain confined to the display, at, for example, point (1312). Conventional on-screen keyboards respond in this way. The operator's line of sight is now 20 degrees to the left of the cursor location. After the dwell period, the quadrant (1308) is selected and Figure 4 is displayed. The cursor hasn't moved. It is now at point (1320). Assume that again the operator attempts to point to the quadrant

25

30

containing the "j" key image (1324) in Figure 4. As the operator turns his head to the right, the cursor immediately moves with him. Thus, the operator's line of sight remains 20 degrees to the left of the cursor location as the cursor moves to the right across the display. The operator must watch the cursor out of his right eye. The problem is aggravated if either the operator cannot  
5 cleanly stop or if he drifts as he dwells. Assume that while attempting to dwell on quadrant (1324) the operator drifts 25 degrees past the bottom of the screen. His line of sight is now 25 degrees below and 20 degrees to the left of the cursor. To correct this misalignment in the conventional quaternary keyboard, the operator must turn his head to the right, "stick" the cursor against the right edge of the display, and continue turning 20 degrees until he has the cursor in his line of sight.  
10 Then he must lift his head until he sticks the cursor against the top edge and continue lifting 25 degrees more. Alternatively, in this scenario, the operator could stick the cursor in the upper right corner of the display and simultaneously rotate his head up and to the right until he brought the cursor into his line of sight.

15 Alignment is also a problematic for NMD operators who use a pointer, such as a mouse, with which the operator indicates by a location on a surface, e.g. a desk top, which corresponds to a desired location on the display, and achieve alignment by removing the pointer from the surface, e.g. lifting the mouse, moving the mouse, then replacing it on the surface. Due to impaired fine motor control, many NMD operators cannot remove a pointer from the surface and replace it on the  
20 surface at a desired location without unintentional movement or extraordinary effort. For these operators, alignment cannot be effectively achieved through conventional means.

In summary, misalignment interferes with accurate pointing and the process of correcting for misalignment may result in the selection of unintended key images.

25 One object of the invention is to allow an operator to align a pointer with a location on a surface.

Another object of the invention is to indicate to an operator a location on a surface with which he may align a pointer.

30 Still another object of the invention is to indicate to an operator when he may align a pointer with a location on a surface.

A further object of the invention is to allow an operator having impaired motor control to align a

pointer with a cursor.

#### G. Length Order

5 As noted previously, one of the elements determining the menu option selection time is the time the operator requires to comprehend the menu options displayed. This time may be reduced if the operator can limit the number of menu options he searches in looking for his desired menu option. Conventional word prediction systems attempt to reduce this operator search time. The operator of a conventional word prediction system may, for example, select the letter "p". The system displays  
10 some number, say six, of the most frequently used words beginning with the letter "p". Conventionally these seven words are displayed either in alphabetic order or in order of frequency of use. Assuming the operator does not see his desired word on the display, he selects another letter, say "r". The system then displays the six most frequently used words beginning with the letters "pr".

15 Searching a displayed list of words in alphabetic order requires that the operator focus his attention on the selection task, as opposed to the information content of the conversation or other task the operator is engaged in. Further, determining whether a given word is alphabetically greater or lesser than a desired word takes substantial time, slowing the selection process. An alphabetically  
20 ordered list is of limited use to an individual who has below normal spelling ability, a frequent problem among individuals with impaired speech. Ordering words by frequency of use often does not limit the number of words the operator must search. The word at the bottom of the displayed list, for example, the sixth most frequently used word beginning with the letters "pr" may be a very common word, even though it is less frequently used than the other five displayed words.

25 One object of the Length Order aspect of the invention is to reduce the time an operator requires to comprehend displayed menu options.

Another object of the Length Order aspect of the invention is to reduce operator search time.

30 Still another object of the Length Order aspect of the invention is to limit the number of menu options an operator searches for in looking for his desired menu option.

A further object of the Length Order aspect of the invention is to speed data entry.

Yet another object of the Length Order aspect of the invention is to increase productivity in speech synthesis for an operator having impaired speech.

#### H. Location Indication

5

The difficulties experienced by NMD operators in pointing to relatively small selectable regions have already been described. One approach to these difficulties is to enlarge the on-screen selectable region, illustrated by the quaternary expansion on-screen keyboard already described. Another approach is the conventional eye gaze system for a speech impaired individual, depicted in  
10 Figure 8. The system consists of a plexiglass frame (6352) having a centrally located aperture (6354). The eye gaze system is positioned between the speech impaired individual and person with whom the speech impaired individual is communicating. There are eight groups of five squares each on the plexiglass frame. Each square within each group of five squares is color coded, e.g. red, blue, green, yellow and clear, matching the color on each of the four corners of the  
15 plexiglass frame. The clear square matches the aperture (6354). All squares are labeled with symbols representing items to be communicated. These labels are not shown in Figure 8. The person with whom the speech impaired individual is communicating observes the eyes of the speech impaired individual to determine the target of the speech impaired individual's eye gaze. To communicate an item, the speech impaired individual gazes first toward the one of the eight groups  
20 of five squares, indicating that he wants to communicate one of the symbols in that group, and gazes second toward one of the four corners and aperture (6354) matching the color of the square labeled with the item to be communicated in the previously indicated group.

Two types of selectable regions are conventionally used in a point and click menu interface in a  
25 graphical user interface. The first, shown in Figure 9, depicts a menu having three menu options, labeled "High", "Medium" and "Low", each displayed on a display (4807), each associated respectively with selectable regions (4801), (4803) and (4805), and each located adjacent the associated selectable region. Figure 10 depicts a menu having the same three menu options, each displayed on a display (4807), each associated respectively with selectable regions (4901), (4903)  
30 and (4905), and each intersecting the associated selectable region. In both these conventional menus, a menu option is selected by pointing to and clicking on the associated selectable region.

Conventional menu hierarchies in automated systems, built from menus of the type shown in Figure 9 or Figure 10, require that the operator proceed sequentially through the steps of searching

menu options, selecting one of them, and, assuming a menu option including a submenu was selected, searching the submenu options, and selecting one of them. Where selection from menu hierarchies constitutes a substantial component of the operator's activities, the slowness of the selection process diminishes productivity.

5

Locating selectable regions or parts thereof outside the display, in accordance with the Perimeter Menu aspect of the invention, allows the large areas outside the display to be used, a major advantage for operators having impaired fine motor control who are unable to maintain a pointer on a small selectable region while selecting by click or by dwell. However, if menu options are displayed on the display near the perimeter of display and near their associated selectable region, the operator has an indication of the location of each selectable region but may not be able to see all the displayed menu options in a glance. Because an operator usually searches a displayed menu for his intended menu option, placing the menu only near the perimeter of the display may increase menu search time, thus increasing menu option selection time.

15

One object of the invention is to indicate to an operator of a menu system having selectable regions outside the display, the menu option associated with each selectable region and the location of each selectable region.

Another object of the invention is to facilitate selection from a menu by an operator having impaired motor control.

Still another object of the invention is to speed selection of a menu option from a menu and of a submenu option from a menu hierarchy.

25

A further object of the invention is to speed speech synthesis for a person having impaired speech and impaired motor control.

#### I. Sound Match

30

Conventional speech recognition systems facilitate computer access for individuals unable to use a standard keyboard whose speech is relatively unimpaired, for example, an individual with quadriplegia, and hands-free computer access for able-bodied individuals. The operator of such a speech recognition system reads a menu option out loud, for example, "open file", and the system.

which includes sound receiving means, for example, a microphone coupled to a sound board having a Digital Signal Processor ("DSP"), receives the sound of the read menu option, digitizes the sound of the read menu option, and then provides the digitized sound to another component of the speech recognition system. sound matching means which includes an application program for  
5 matching the digitized sound to one of a plurality of sounds, each representing respectively the sound of a spoken menu option. The system determines which sound best matches the sound of the read menu option and selects the menu option associated with this best matched sound.

Individuals whose speech is impaired are often unable to effectively use conventional speech  
10 recognition systems because they often cannot produce a large distinct variety of sounds characteristic of phonetic languages. For example, such an individual may produce similar sounds for the two consonants "t" and "d" so that these sound are indistinguishable to a conventional speech recognition system, or such an individual may not be able to consistently produce sounds distinguishable by a speech recognition system, resulting in false matches. Other symptoms of  
15 impaired speech, for example, similarities among certain phonemes and impaired ability to start or stop sound production appropriately, may substantially limit the variety of sounds distinguishable to a conventional speech recognition system an individual may consistently produce.

Conventional speech recognition systems provide limited capabilities in languages rich in  
20 homophones, for example, Chinese, because in such languages, a distinct sound is often insufficient to specify a word, as is described in the Background Art section of the Ideographic Languages aspect of the invention. The problem may be briefly illustrated by an example. Suppose a Chinese data entry operator using a conventional speech recognition system speaks the phonetic unit "fu" with a particular intonation. This distinct sound may well have over 15  
25 homophones. Although the operator could use the keyboard to select one of these 15 homophones, this defeats the purpose of speech recognition, which is to facilitate hands-free computer access.

One object of the invention is to facilitate selection from a menu, and, in particular, from a menu of  
30 homophones.

Another object of the invention is to facilitate speech synthesis and voice activated computer access by individuals with speech impairments.

Still another object of the invention is to speed data entry in Ideographic Languages.

## J. Ideographic Language

The use of ideographs as the graphic symbols in written languages is found in many parts of the world. An ideograph, as used herein, is a graphic symbol used to represent an object, an idea or a word, without expressing, as in a phonetic system, the specific sounds forming the verbal expression of the object, idea or word. Ideographic languages include Chinese, Japanese and Korean. A graphic symbol, as used herein, includes, but is not limited to, each of the following: a letter of an alphabet, a Japanese kana, and an ideograph. For purposes of illustrating the concepts of the present invention specific reference will be made herein to a preferred embodiment of the system and method as it applies to the Chinese language.

In modern Chinese, a repertoire of between 2500 and 3000 ideographs is necessary to achieve normal business adequacy in reading and writing, while the language itself has approximately 50,000 ideographs that have been identified historically, with about 10,000 ideographs in current use. The conventional keyboard, with approximately 100 keys, is designed for languages with phonetic scripts, such languages having a small set of graphic symbols, i.e. letters. If such a keyboard were to be used in a corresponding manner for the direct input of Chinese ideographs, it would require many thousands of keys since, unlike western phonetic languages, Chinese has many thousands of ideographs. Selection of an ideograph from such a keyboard would require the operator to search a great many keys for the desired key, and thus be impracticably slow.

Prior art methods for selecting Chinese ideographs make use of various ideograph classification systems known to Chinese speakers. The operator first specifies a class of ideograph, based on a first characteristic common to many ideographs. Ideographs having that common characteristic are displayed and the operator selects from among them, either directly, by selecting an individual ideograph, or indirectly, by specifying a second common characteristic usually dependent upon the first characteristic, thus further limiting the displayed ideographs to those having both the first and second common characteristics. In some prior art methods, the operator may continue to specify characteristics until he has specified a unique ideograph.

One ideograph classification system is called the Pin Yin System. This classification system uses the phonetic structure of the Chinese language. In spoken Chinese there are approximately 412 basic phonetic units, each having a monosyllabic sound, for example, "nee", "how" and "ma". Four intonations can potentially be applied to each phonetic unit, resulting in approximately 1280

distinct sounds. With 10,000 ideographs in current use, each represented by one of approximately 1280 distinct sounds, it is evident that many Chinese ideographs are homophones, i.e. have the same sound. Over 80% of Chinese ideographs have homophones. The Pin Yin System uses this limited number of phonetic units as the basis for its classification. Ideographs which are  
5 homophones are classified together; the common characteristic of the Pin Yin System is the distinct sound.

According to the Pin Yin and Zhu Yin coding methods, known in the prior art, the operator specifies a distinct sound using a keyboard labeled with symbols representing the Latin alphabet  
10 (Pin Yin method) or Chinese phonetic units (Zhu Yin method). The first key operation or sequence of key operations specifies the phonetic unit. The second key operation specifies the intonation. In general, less than 15 ideographs have this sound, though in some cases there are many more homophones. These are displayed and the user selects from among them. In such cases, the operator, depending upon the system, may page through matching ideographs or specify another  
15 common characteristic to further limit the number of ideographs displayed. A common characteristic which may be used at this stage exploits another feature of the Chinese language. The majority of Chinese words are expressed by a combination of two ideographs, the meaning of the paired ideographs has its own meaning which may or may not be related to that of the constituent ideographs. Assuming the operator has specified a first distinct sound matching 40  
20 ideographs, he may specify a second distinct sound which alone may match, for example, 20 ideographs, but there may be only two ideograph pairs having the specified first and second distinct sounds in that order. Thus, a second common characteristic may limit matching ideograph pairs to a number sufficiently small for the operator to efficiently search and select from, or may uniquely specify an ideograph pair. Another common characteristic the operator may specify to limit the  
25 number of matching ideographs is a meaning or meaning class to which one or more sequences of one or more ideographs belong.

Yet another feature of the Chinese language which may be exploited to limit the number of matching sequences of ideographs is the ideograph block. An ideograph block is a sequence of  
30 four ideographs which together has its own meaning which may or may not be related to that of the constituent ideographs. As above, where the operator specified a distinct sound for the second of two ideographs of an ideograph pair, so may the operator specify a distinct sound for the second, third and/or fourth ideograph of an ideograph block, to limit the number of matching ideograph blocks.

Another conventional ideograph classification system makes use of a classification of parts of ideographs. Ideographs are built from a set of 214 components, called radicals. Different radicals, perhaps placed within different locations within an ideograph, are combined to create an ideograph. According to the Chan Jie coding method, known in the prior art, the operator specifies one or  
5 more radicals appearing in the ideograph he wishes to enter. He may, for example, use a keyboard having at least 214 keys, each corresponding to a radical, or may actuate a sequence of keys, the sequence corresponding to a radical. Other common characteristics the operator may specify to limit the number of matching ideographs include a phonetic unit, the first brush stroke, and the last brush stroke used to draw the ideograph.

10 Another conventional ideograph classification system makes use of a classification of parts of ideographs. According to the Four Corner coding method, known in the prior art, the operator specifies the classification of the four corners of the ideograph he wishes to enter. Other common characteristics the operator may specify to further limit the number of matching ideographs include  
15 the number of horizontal strokes used to draw the ideograph, and the classification of a certain part of the ideograph above the lower right corner.

Yet another conventional ideograph classification system makes use of a classification ideographs based on the basic strokes from which each ideograph is built. In Chinese, there are a limited  
20 number of basic strokes, each ideograph being composed of between 1 and 33 such strokes. Ideographs may be classified by a small number of basic strokes, preferably according to strict rules regarding the order of stroke entry. In one conventional application of this coding method, the operator specifies only the first and last basic strokes of the desired ideograph, then selects from a display of all ideographs sharing this first-last basic stroke combination.

25 Japanese is somewhat more complicated than Chinese. In addition to ideographs, the Japanese language uses graphic symbols called kana, which includes hiragana and katakana. In written Japanese, ideographs are frequently combined with kana. Kana may be may specified phonetically, for example, to designate the hiragana pronounced "ko" an operator of a Japanese word processing  
30 system may type "k" and then "o" on a Latin alphabetic keyboard or may type a single key associated with this hiragana. Kana has multiple uses in a Japanese word processing system. Kana may represent itself, since kana may stand alone in Japanese text. Alternatively, kana may be used to specify Japanese ideographs, either by specifying the radicals which compose Japanese ideographs or by specifying the pronunciation of Japanese ideographs. A sequence of phonetic

units specified by kana may represent that sequence of kana, a single Japanese ideograph, multiple Japanese ideographs, or a combination of one or more Japanese ideographs and one or more kana. In addition, a single Japanese ideograph may have multiple pronunciations, including a Japanese pronunciation and a Chinese pronunciation, and may have multiple kana spellings.

5

Conventional word processing systems for ideographic languages suffer from certain deficiencies. First, in systems where the operator specifies common characteristics until he has uniquely specified an ideograph, the operator must be extensively trained in the particular classification system. Depending upon the system, the operator may need to know, for example, how many  
10 horizontal brush strokes are required to draw a desired ideograph, or each of the 214 radicals and the encoding of each of them on a keyboard having less than 214 keys. Second, in systems where the operator uses both hands on the keyboard to specify a common characteristic, then selects from among ideographs, ideograph pairs or ideograph blocks by operating a function key or by pointing to one of the options with a mouse or other hand operated pointer and then operating a switch, the  
15 operator lifts one of his hands from the keyboard, makes the selection and then moves his hand back to the keyboard to specify another common characteristic. This sequence occurs often and contributes to the slow average rate of word entry (approximately 20 words per minute) for Chinese relative to alphabetic languages. Another problem in these systems is that the display of ideographs for selection may obscure part of the image of the previously entered ideographs or  
20 other information on the display.

Another drawback of many word processing systems for ideographic languages relates to the ease of copying a document. Ideally, the operator concentrates on the document to be copied, only occasionally scanning text he has input. For those word processing systems that display ideographs  
25 on a display for the operator's selection, the operator must frequently shift his gaze from the document to the display and back again. The operator cannot concentrate on both the document and the display simultaneously.

Ideographs, as used herein, also include the symbols of symbol sets used for communication by  
30 individuals who have hearing, speech or language impairments, for teaching literacy skills to those lacking them, including pre-literate children and individuals with intellectual disabilities, and for international written communication. These symbol sets include, but are not limited to, each of the following: Picture Communication Symbols, Rebus, Picsym, Pictogram Ideogram Communication Symbols, Yerkish, Blissymbolics and depictions of the signs of a manual sign language. Examples

of symbols of the Picture Communication Symbols, Rebus, Picsyms, and Blissymbolics symbol sets are shown in Figure 11, Pictogram Ideogram Communication Symbols in Figures 12(a) - 12(d) and Yerkish in Figures 13(a) - 13(j). Picture Communication Symbols, Rebus, Picsyms, Pictogram Ideogram Communication Symbols, Yerkish, and Blissymbolics are each described in

5 Beukelman, David R. & Mirenda, Pat, Augmentative and Alternative Communication, Management of Severe Communication Disorders in Children and Adults, Paul H. Brookes Publishing Co., 1992, pp. 22-29.

Individuals who have not acquired or who have lost their literacy skills may use symbolic symbol

10 sets in learning to read. If the individual lacks fine motor control, for example, due to cerebral palsy, the individual's disability may inhibit the acquisition of literacy skills by, for example, inhibiting repetition of an exercise by the individual, by limiting the individual's ability to participate in the classroom, or by making skill assessment by a teacher difficult so that the teacher may incorrectly believe that remediation is necessary or that a particular skill has been mastered. If

15 the individual also has impaired speech, literacy acquisition is more difficult still.

Conventional literacy training systems for individuals who are unable to use a standard keyboard or mouse use switch access, often in combination with scanning. As already described, scanning is an

20 extremely slow process. Moreover, as the number of symbols in the symbol set increases, the time required to select a symbol also increases. Of the symbol sets mentioned above, Picture Communication Symbols contains approximately 1800 symbols, Rebus contains approximately 800 symbols, Picsyms contains approximately 1800 symbols, Pictogram Ideogram Communication Symbols contains approximately 400 symbols and Blissymbolics contains approximately 1400 symbols. When using a system with a static display, the operator may expend considerable time

25 and effort finding the desired symbol; when using a system with a dynamic display, the operator may expend considerable time effort memorizing and recalling where a particular symbol is located within a hierarchy of symbols. This time and effort generally does not contribute to the acquisition of literacy skills.

30 One object of the invention is to display a menu of sequences of one or more ideographs on a display so that a large contiguous area on the display is not obstructed by the menu.

Another object of the invention is to facilitate ideograph entry in word processing systems for the Chinese, Japanese and Korean languages.

Still another object of the invention is to speed selection of sequences of graphics including one or more ideographs.

Yet another object of the invention is to allow an operator of a word processing system for an ideographic language to select a sequence of one or more ideographs without lifting either hand from the keyboard.

A further object of the invention is to indicate to an operator the progress toward selection of a dwell-selectable sequence of one or more ideographic characters.

A still further object of the invention is to synthesize speech for an operator having impaired speech.

Additional objects, advantages and novel features of the invention will be set forth in part in the description which follows, and in part will become apparent to those skilled in the art upon examination of the following or may be learned by practice of the invention. The objects and advantages of the invention may be realized and attained by means of the instrumentalities and combinations particularly pointed out in the appended claims.

## Disclosure of Invention

### A & B. Perimeter Menu and Confinement

According to the present invention, the objects mentioned in the Background Art section describing the above aspects of the invention and other objects and advantages are attained by an apparatus for selecting a menu option from a menu. Each menu option is associated respectively with a selectable region on a display area. The apparatus includes (a) the display area; (b) means for delimiting a plurality of selectable regions, each of the selectable regions associated respectively with a menu option and each of the selectable regions including an invisible subregion adjacent the display area and a visible subregion on the display area, the plurality of visible subregions together at least partially circumscribing a region on the display area; (c) movement related signal receiving means for receiving a movement related signal indicating a location; and (d) selection means for

selecting, in response to a selection event, the menu option associated with the selectable region intersected by the location indicated by the movement related signal.

5 Additionally, the objects mentioned in the Background Art section describing the above aspects of the invention and other objects and advantages are attained by a method of selecting a menu option from a menu. The menu options are each respectively associated with a selectable region on a surface which includes a display area. The selectable regions together at least partially circumscribe a region on the display area. An operator indicates a location on the surface with a body member. The method comprises the steps of: (a) confining the location indicated by the  
10 body member of the operator to the display area; and (b) selecting, in response to the period of one or more intersections of the location indicated by the movement related signal and any one selectable region equalling or exceeding a predetermined period, the menu option associated with the intersected selectable region.

15 The method and apparatus of the aspect of the invention disclosed above and other aspects of the invention permits an NMD operator to utilize for computer access his relatively unimpaired motor capabilities, in particular, gross motor control, in lieu of, or as a supplement to, his impaired motor capabilities. The method and apparatus of the invention also reduces the interference of menu option displays with the display of information.

20

### C. Dwell

According to the present invention, the objects mentioned in the Background Art section describing the above aspect of the invention and other objects and advantages are attained by an apparatus for  
25 indicating dwell time comprising a surface having a region thereon; movement receiving means for receiving a movement related signal indicating successive locations; and indicating means for indicating at least the duration of a period of intersection of two or more of the successive locations indicated by the movement related signal and the region.

30 Additionally, the objects mentioned in the Background Art section describing the above aspect of the invention and other objects and advantages are attained by a method of indicating dwell time comprising the steps of displaying a selectable region on a surface; receiving a movement related signal indicating a first location intersecting the region and, at a later time, a second location intersecting the region; and indicating the difference between the time of the second location and

the time of the first location.

#### D. Path Directness

5 According to the present invention, the objects mentioned in the Background Art section describing the above aspect of the invention and other objects and advantages are attained by an apparatus for selecting a menu option from a menu. Each menu option is associated respectively with a selectable region shown on a surface. The apparatus includes (a) means for moving a cursor on the surface in response to a movement related signal, for example, a computer program which moves a  
10 cursor on the surface reflecting the operator's movement of a mouse; and (b) means for selecting the menu option associated with the selectable region most nearly along a cursor path (1) prior to an intersection of the cursor and the selectable region most nearly along the cursor path, (2) upon intersection of the cursor and the selectable region most nearly along the cursor path, or (3) in response to the period of intersection equalling or exceeding a predetermined period.

15

Also according to the present invention, the objects mentioned in the Background Art section describing the above aspect of the invention and other objects and advantages are also attained by a method for selecting a menu option from a menu. Each menu option is associated respectively with a selectable region shown on a surface. The method includes the steps of (a) displaying the  
20 selectable regions on the surface, (b) detecting a movement related signal and in response moving a cursor on the surface, and (c) selecting the menu option associated with the selectable region most nearly along a cursor path (1) prior to an intersection of the cursor and the selectable region most nearly along the cursor path, (2) upon intersection of the cursor and the selectable region most nearly along the cursor path, or (3) in response to the period of intersection equalling or exceeding  
25 a predetermined period.

In accordance with the present invention, the objects mentioned in the Background Art section describing the above aspect of the invention and other objects and advantages are attained by an apparatus for measuring an individual's ability to move one of the individual's body members  
30 directly from a starting position to an ending position. The apparatus includes: (a) receiving means for receiving a sampling among data indicative of successive positions of the body member; and (b) measurement means for measuring any deviation of the path indicated by the received position data from a direct path between the starting position and the ending position.

The objects mentioned in the Background Art section describing the above aspect of the invention and other objects and advantages are also attained, according to the present invention, by a method for measuring an individual's ability to move one of the individual's body members directly from a starting position to an ending position. The method includes the steps of: (a) receiving a sampling  
5 among data indicative of successive positions of the body member; and (b) measuring any deviation of the path indicated by the received position data from a direct path between the starting position and the ending position.

#### E. Intersection

10 According to the present invention, the objects mentioned in the Background Art section describing the above aspect of the invention and other objects and advantages are attained by an apparatus for selecting an option from a menu. The apparatus comprises cursor movement means for receiving a movement related signal and for moving a cursor on a display responsive to the received movement  
15 signal; delimit means for delimiting with respect to the display a first plurality of regions and a second plurality of selectable regions, each of the first plurality of regions associated respectively with one of the second plurality of selectable regions, each of the second plurality of selectable regions associated respectively with a menu option, wherein at least one of the first plurality of regions is not coterminous with its associated one of the second plurality of selectable regions; and  
20 selection means, responsive to an intersection of the cursor and any one of the first plurality of regions and to a selection event associated with the one of the second plurality of selectable region associated with the intersected one of the first plurality of regions, for selecting the menu option associated with the selectable region associated with the selection event.

25 According to the present invention, the objects mentioned in the Background Art section describing the above aspect of the invention and other objects and advantages are also attained by a method of selecting an option from a menu, said method comprising the steps of: receiving a movement related signal and moving a cursor on a surface responsive thereto; delimiting a first plurality of regions and a second plurality of selectable regions with respect to a surface, each of the first  
30 plurality of regions associated respectively with one of the second plurality of selectable regions, each of the second plurality of selectable regions associated respectively with a menu option; wherein at least one of the first plurality of regions is not coterminous with its associated one of the second plurality of selectable regions; and responsive to an intersection of the cursor and any one of the first plurality of regions and to a selection event associated with the one of the second

plurality of selectable region associated with the intersected one of the first plurality of regions, selecting the menu option associated with the selectable region associated with the selection event.

#### F. Alignment

5

Confining the cursor to the display or to a polygon on the display, in accord with the Perimeter Menu aspect of the invention, facilitates selection from a perimeter menu. However, for an operator who overshoots a perimeter menu option, confining the cursor to the display results in a loss of alignment between the cursor and the location indicated by the operator, necessitating an apparatus and method for realignment.

10

According to the present invention, the objects mentioned in the Background Art section describing the above aspect of the invention and other objects and advantages are attained by an apparatus, including a surface on which may be displayed a moveable cursor, said apparatus allowing an operator to align a pointer with a predetermined location on the surface. The apparatus includes a display means for displaying the cursor on the surface; movement related signal receiving means for receiving a movement related signal; and control means for moving the cursor in response to the movement related signal and for thereafter inhibiting movement of the cursor for a first period of time in response to an operator action detected by the movement related signal receiving means.

20

According to the present invention, the objects mentioned in the Background Art section describing the above aspect of the invention and other objects and advantages are also attained by a method, for use in a system comprising a pointer and a surface on which is displayed a first cursor whose movement on the surface is responsive to the movement of the pointer, of aligning the first cursor with a predetermined location on the surface. The method includes the steps of: (a) producing the first cursor on the surface; (b) moving the first cursor responsive to the movement of the pointer, said movement restricted to a region on the surface; and then (c) responsive to an operator action, producing a second cursor at a predetermined location on the surface for a period of time; and (d) moving the first cursor in or in close proximity to the predetermined location..

25

30

#### G. Length Order

According to the present invention, the objects mentioned in the Background Art section describing the above aspect of the invention and other objects and advantages are attained by an apparatus for

use in a menu interface system. The apparatus orders a plurality of named menu options at least in part according to the order of the length of each of the names of the name menu options, and then displays the named menu options in that order

5 According to the present invention, the objects mentioned in the Background Art section describing the above aspect of the invention and other objects and advantages are also attained by a method of data entry for use with a computer. According to the method, a plurality of named menu options are displayed at least in part according to the order of the length of each of the names of the name menu options. Each named menu option is associated respectively with a sequence of one or more  
10 characters. A selection event is associated with one of the named menu options and the sequence of one or more characters associated with the selected named menu option is input to an application program executing on the computer.

#### H. Location Indication

15 According to the present invention, the objects mentioned in the Background Art section describing the above aspect of the invention and other objects and advantages are attained by an apparatus for indicating the location of the selectable region associated with a menu option. Each menu option is associated respectively with a selectable region. The apparatus includes (a) means for at least  
20 partially delimiting the selectable regions; and (b) indication means for displaying each menu option such that the displayed menu option indicates the location of the associated selectable region. None of the displayed menu options intersects the selectable region associated therewith.

According to the present invention, some of the objects mentioned in the Background Art section  
25 describing the above aspect of the invention and other objects and advantages are also attained by a method of indicating the location of the selectable region associated with a submenu option in a menu hierarchy. The method comprises the steps of: at least partially delimiting the plurality of selectable regions; and displaying a plurality of submenu indicating regions. Each submenu indicating region is associated respectively with one of the submenu options and each submenu  
30 indicating region is displayed in a manner indicating the location of the selectable region associated with the submenu option associated with the submenu indicating region.

#### I. Sound Match

According to the present invention, the objects mentioned in the Background Art section describing the above aspect of the invention and other objects and advantages are attained by an apparatus for selecting a menu option from a plurality of menu options. Each menu option is displayed on a display and associated respectively with a sound. The apparatus includes: (a) means for displaying  
5 the menu on the display; (b) means for receiving a sound signal; (c) means for matching the received sound signal to any one of sounds; and (d) means for selecting the menu option associated with the matched sound.

According to the present invention, some of the objects mentioned in the Background Art section  
10 describing the above aspect of the invention and other objects and advantages are also attained by a method of selecting a sequence of one or more graphic symbols from a plurality of sequences of one or more graphic symbols, one or more sequences of the plurality of sequences including one or more ideographs. The method comprises the steps of displaying on a display the plurality of sequences, each of the plurality of sequences having a common characteristic and each associated  
15 respectively with a sound indicator; matching a sound to any one of the plurality of sound indicators; and selecting the sequence of the plurality of sequences associated with the matched sound indicator.

#### J. Ideographic Languages

20 According to the present invention, the objects mentioned in the Background Art section describing the above aspect of the invention and other objects and advantages are attained by a method for selecting a single sequence of one or more ideographs from a menu of several such sequences. Each sequence is respectively associated with a selectable region on a surface which includes a  
25 display area. The selectable regions together at least partially circumscribe a region on the display area. An operator indicates a location on the surface with a body member. The method comprises the steps of: (a) displaying the selectable regions on the surface so that they at least partially circumscribe a region on the display area; and (b) selecting, in response a selection event, the sequence indicated by the operator.

30 Still other objects and advantages of the present invention will become readily apparent to those skilled in this art from the following detailed descriptions, wherein I have shown and described the preferred embodiment of each aspect of the invention, simply by way of illustration of the best mode contemplated by me of carrying out each aspect of my invention. As will be realized, each

aspect of the invention is capable of other and different embodiments, and its several details are capable of modifications in various obvious respects, all without departing from the invention. Accordingly, the drawings and descriptions are to be regarded as illustrative in nature, and not as restrictive.

5

#### Brief Description of Drawings

FIG. 1 is an illustration of a display showing a conventional on-screen keyboard.

10

FIG. 2 is an illustration of a display showing a conventional on-screen keyboard and output from a word processing application program.

FIG. 3, 4 and 5 are each illustrations of the display of each step of letter selection using a conventional quaternary on-screen keyboard.

15

FIG. 6 is an illustration of a display showing a conventional quaternary on-screen keyboard and output from two application programs.

FIG. 7 is an illustration of a conventional device implementing joystick patterns.

20

FIG. 8 is an illustration of a display of a conventional eye gaze system.

FIG. 9 and 10 are each illustrations of a display showing a conventional menu.

25

FIG. 11 depicts examples of symbols from the Picture Communication Symbols, Rebus, PicSym and Blissymbols symbol sets.

FIG. 12(a) - FIG. 12(d) depict examples of symbols from the Pictogram Ideogram Communication Symbols symbol set.

30

FIG. 13(a) - FIG. 13(j) depict examples of symbols from the Yerkish symbol set.

FIG. 14 is a block diagram of a computer which may be utilized in accordance with the present

invention.

FIG. 15 is a block diagram of a speech synthesis system which may be utilized in accordance with the present invention.

5

FIG. 16 is an illustration of software components of an apparatus in accordance with an embodiment of the Perimeter Menu aspect of the invention.

10

FIG. 17 and 18 are each illustrations of a display and structures in accordance with an embodiment of the Perimeter Menu aspect of the invention.

FIG. 19 is an illustration of a display and structures in accordance with another embodiment of the Perimeter Menu aspect of the invention.

15

FIG. 20 is an illustration of a display and structures in accordance with still another embodiment of the Perimeter Menu aspect of the invention.

FIG. 21 is an illustration of a display and structures in accordance with another embodiment of the Perimeter Menu aspect of the invention.

20

FIG. 22 is an illustration of a display and structures in accordance with yet another embodiment of the Perimeter Menu aspect of the invention.

25

FIG. 23 is an illustration of an apparatus in accordance with a further embodiment of the Perimeter Menu aspect of the invention.

FIG. 24 and 25 are each illustrations of a display and structures in accordance with another embodiment of the Perimeter Menu aspect of the invention.

30

FIG. 26 and 27 illustrate an apparatus in accordance with still another embodiment of the Perimeter Menu aspect of the invention. Figure 26 depicts a front view of the apparatus. Figure 27 depicts a cut away view from the top of the apparatus.

FIG. 28 is a top view of a headrest in accordance with an embodiment of the Perimeter Menu

aspect invention.

FIG. 29 and 30 illustrate the state table aPocketFsm in accordance with the preferred embodiment of the Perimeter Menu aspect of the invention.

5

FIG. 31 is an illustration of a display and structures in accordance with the preferred embodiment of the Confinement aspect of the invention.

FIG. 32 is an illustration of a display and structures in accordance with another embodiment of the Confinement aspect of the invention.

10

FIG. 33 is an illustration of a display and structures in accordance with another embodiment of the Confinement aspect of the invention.

FIG. 34 is an illustration of an apparatus in accordance with the Dwell aspect of the invention and with the Path Directness aspect of the invention.

15

FIG. 35 is an illustration of another apparatus in accordance with the Dwell aspect of the invention.

FIG. 36 is an illustration of still another apparatus in accordance with the Dwell aspect of the invention.

20

FIG. 37 is an illustration of yet another apparatus in accordance with the Dwell aspect of the invention.

25

FIG. 38 is an illustration of another apparatus in accordance with the Dwell aspect of the invention.

FIG. 39 is an illustration of a display and structures in accordance with the preferred embodiment of the Path Directness aspect of the invention.

30

FIG. 40 is an illustration of a display and structures in accordance with an embodiment of the Path Directness aspect of the invention.

FIG. 41 is an illustration of a display and structures in accordance with another embodiment of the

Path Directness aspect of the invention.

FIG. 42 is an illustration of a display and structures in accordance with another embodiment of the Path Directness aspect of the invention.

5

FIG. 43 is an illustration of a display and structures in accordance with another embodiment of the Path Directness aspect of the invention.

10

FIG. 44, 45 and 46 are each illustrations of a display and structures in accordance with the preferred embodiment of the Intersection aspect of the invention.

FIG. 47 and 48 are each illustrations of a display and structures in accordance with another embodiment of the Intersection aspect of the invention.

15

FIG. 49, 50 and 51 are each illustrations of a display and structures in accordance with the preferred embodiment of the Alignment aspect of the invention.

20

FIG. 52 is an illustration of a display and structures in accordance with the preferred embodiment of the Location Indication and the Length Order aspects of the invention.

FIG. 53 is an illustration of a display and structures in accordance with an embodiment of the Location Indication aspect of the invention.

25

FIG. 54 and 55 are each illustrations of a display and structures in accordance with another embodiment of the Location Indication aspect of the invention.

FIG. 56 is an illustration of a display and structures in accordance with a still further embodiment of the Location Indication aspect of the invention.

30

FIG. 57 is an illustration of a display and structures in accordance with a further embodiment of the Location Indication aspect of the invention.

FIG. 58 and 59 are illustrations of a display and structures in accordance with the preferred embodiment of the Sound Match aspect of the invention.

FIG. 60 is an illustration of a display and structures in accordance with another embodiment of the Sound Match aspect of the invention.

FIG. 61 is an illustration of a display and structures in accordance with another embodiment of the Sound Match aspect of the invention.

FIG. 62 is a block diagram of a speech recognition system which may be utilized in accordance with the Sound Match aspect of the invention.

FIG. 63 is an illustration of software components of an apparatus in accordance with an embodiment of the Sound Match aspect of the invention.

FIG. 64 is an illustration of a display and structures in accordance with the preferred embodiment of the Ideographic Language aspect of the invention.

FIG. 65 is an illustration of a display and structures in accordance with another embodiment of the Ideographic Language aspect of the invention.

FIG. 66 is an illustration of a display and structures in accordance with still another embodiment of the Ideographic Language aspect of the invention.

FIG. 67 is an illustration of a display and structures in accordance with yet another embodiment of the Ideographic Language aspect of the invention.

### Best Mode for Carrying Out the Invention

The hardware and software operating environment of the preferred embodiment of all aspects of the invention will now be described with reference to a particular embodiment of the invention, hereinafter "prototype". The prototype of the invention illustrates the best mode of practicing each aspect of the invention known by me except where a preferred mode is described.

Figure 15 depicts a block diagram of the hardware components of the prototype (2214), including a conventional general purpose computer system (2218), an optional pointer (2202), an optional

printer (2220) and a speech synthesizer (2206). The general purpose computer system (2218) includes a conventional computer system (2116), a storage unit (2208), a keyboard (2210), and a diskette drive (2216). Figure 14 depicts a block diagram of the conventional computer system (2116), including a processing unit (2102) and a display (2112). The processing unit (2102) includes a processor (2104), a memory (2106) and control circuitry (2108). The prototype employs the Toshiba T6400DXC general purpose computer system manufactured by Toshiba Corporation, Kawasaki, Japan. However, the T6400DXC is preferably substituted with the IBM ThinkPad 755C computer system, part number 9545F0C, manufactured by IBM Corporation, Armonk, New York, USA, because the former requires a 110VAC power source while the latter is powered by an integral battery. An integral battery allows an NMD operator to use the system when a 100VAC source is not available or when attaching to a 110VAC power source is inconvenient. The prototype further includes a head mounted pointer communicating via an infrared link with the computer system so that there are no cables tethering the operator to the computer system. Any cable between the operator and the computer system would have to be connected, probably by an attendant since the operator may lack the fine motor skills required to make such a connection. Preferably computer access can be accomplished independently by the operator. The choice of a pointing device is primarily dictated by the particular capabilities of the operator. Usually the best pointing device for a particular operator is the one drawing on that operator's best motor control. For example, if an operator's foot control is superior to his head control, a pointing device using his foot is preferably to a head pointer.

The prototype employs the Remote Headmaster® manufactured by the Prentke Romich Company, Wooster, Ohio, USA. However, the combination of the HeadMaster® Plus, part number HM-1P, HeadMaster® Plus Remote Adapter, part number HM-RA, and HeadMaster® Plus Laptop Adapter, part number HM-LA, all available from the Prentke Romich Company, is preferable because the headset is more comfortable and the HeadMaster® Plus ultrasonic transmitter mounts more easily on a laptop computer system than the Remote Headmaster ultrasonic transmitter.

The preferred embodiment further includes a battery powered printer, the MobileWriter®, part number 730879, manufactured by Mannesmann Tally Corporation, Kent, Washington, USA and a speech synthesizer, the Multivoice Speech Synthesizer, part number MV2-SS, manufactured by The Institute on Applied Technology, Children's Hospital, Boston, Massachusetts, USA.

The pointer (2202) is a device which provides data concerning the relative or absolute position of

the operator or any body member of the operator. The display (2112) and pointer (2202) together provide for the interactive nature of the general purpose computer system (2218) in that, in accord with the various aspects of the invention, the interpretation that the processor (2104) gives to a certain pointer action made by the operator depends, in the majority of situations, upon what is being displayed to the operator at that time.

The prototype (2214) shown in Figure 15 further includes a keyboard (2210), which functions to provide input from an able-bodied operator to the general purpose computer system (2218). The keyboard (2210) is useful for configuration, diagnostic and backup purposes, functions which are performed relatively infrequently and usually require an able-bodied person for ancillary activities, for example, loading backup media into the general purpose computer system. The prototype (2214) also optionally includes a printer (2220) which functions to provide hard copy output of data developed or stored in the general purpose computer system, and a speech synthesizer (2206), which functions to provide speech output for utterances and words composed using or retrieved from the general purpose computer system (2218).

The couplings between the devices depicted in Figure 15 may be made by any means which permits the orderly and timely exchange of data across the interface. In the preferred embodiment, the interfaces between the pointer (2202) and the general purpose computer system (2218) and between the general purpose computer system (2218) and the speech synthesizer (2206) conform to the Electronic Industries Association RS-232 interface specification. The interface between the general purpose computer system (2218) and the printer (2220) conform to the Centronix 50 pin parallel interface specification.

The software component of the prototype are stored in memory (2106) and executed on the processing unit (2102). The software component of the prototype, depicted in Figure 16, include a software driver (1202), an operating system (1204), an optional database program (1210), and the prototype access program code and data, hereinafter collectively referred to as the "access program" (1206). In the preferred embodiment, one or more application programs (1208) may also execute on the processing unit (2102) and accept control and data from the access program (1206) via the operating system (1204). The software driver (1202) of the prototype is the Logitech Mouse Driver included with Windows® version 3.1. The operating system (1204) of the prototype is Windows® version 3.1 in combination with MS-DOS® version 6.2. Hereinafter, the operating system is referred to simply as "Windows®", available from Microsoft Corporation, Redmond.

Washington, USA.

The optional database program (1210) is described in the detailed description of the Length Order aspect of the invention. The prototype access program (1206) is described in detail below.

5

As stated earlier, the software components of the prototype are stored in memory (2106).

Depending on the capacity of memory (2106) and the size of the application programs, portions of these programs may be transferred as needed between memory (2106) and the storage unit (2206) or between memory (2106) and a diskette in the diskette drive (2216) depicted in Figure 15. The  
10 basic function of the storage unit (2206) and the diskette drive (2216) is to store programs and data that are employed by the general purpose computer system (2218) and which may readily be transferred to the memory (2106) when needed.

It is to be understood that components others than those used in the prototype may be utilized in  
15 accordance with the invention. It is only necessary that the substitute component or components have the capacity to carry out the functions described. For example, the processing unit of the general purpose computer system may be substituted with a microprocessor coupled to custom electronics for performing the functions of the various aspects of the invention, or the color display of the prototype may be substituted with a monochrome display.

20

#### A. Perimeter Menu

The preferred embodiment of the Perimeter Menu aspect of the invention will now be described in detail from a functional perspective using an example. This description refers to selectable regions  
25 which include one or more subregions. A selectable region is a region, delimited with respect to a display or a surface, and associated with a menu option which may be selected, usually by a selection event. A subregion is a selectable region that is included within another selectable region. Thus a subregion is, by itself, a selectable region. Assuming that a certain selectable region includes subregions A and B, dwell time on subregions A and B may be combined, for example, by  
30 summing, so that dwelling on either subregion A or B or a combination of both for the selection threshold period selects the menu option associated with the selectable region.

Reference will now be made to Figures 17 and 18 which depict an example of the preferred embodiment of the Perimeter Menu aspect of the invention. Figure 17 shows the display (2112) of

a general purpose computer system (2218 in Figure 15) and eight selectable regions. Each of the eight selectable regions consists of the union of a visible subregion on the display (2112) and an invisible subregion located outside the display (2112) and adjacent the visible subregion. For example, the selectable region at 11 o'clock in Figure 17 labeled with menu option "vort<space>x" consists of invisible subregion (0104) and visible subregion (0106), and within this description of the Perimeter Menu aspect of the invention is referred to as selectable region (0104/0106). The other selectable regions shown in Figure 17, proceeding counter clockwise from selectable region (0104/0106) are (0108/0110), (0112/0114), (0116/0118), (0120/0122), (0124/0126), (0128/0130) and (0132/0134). Each subregion may be sized to suit the operator's preferences and abilities.

Each selectable region is associated respectively with a menu option. In Figure 17, selectable region (0104/0106) is associated with menu option vort<space>x, selectable region (0108/0110) with menu option "sumac", selectable region (0112/0114) with menu option "wizen", selectable region (0116/0118) with the menu option undo indicated by an icon on visible subregion (0118) representing an undo function, selectable region (0120/0122) with menu option "words", selectable region (0124/0126) with menu option "talk", selectable region (0128/0130) with menu option "ldhbfk" and selectable region (0132/0134) with menu option "ypgqj,". Together, the eight visible subregions circumscribe region (0150) on the display.

Selectable regions may be delimited by data indicative of one or more boundaries of the selectable region. Equivalently, the delimit means may be detectors operative to determine when the location indicated by the movement related signal has crossed one of those boundaries or intersects a selectable region. A partially delimited region or subregion is one which is unbounded on at least one side.

Resuming, now, with the example, to select a menu option associated with a selectable region the operator moves a pointer (2202 in Figure 15) coupled to the general purpose computer system (2218 in Figure 15) to indicate a location on the selectable region, including either subregion, associated with the desired menu option and maintains the indicated location on the selectable region for the selection threshold period. The period of time required for selection may vary responsive to the proximity of the indicated location to the location of a cursor on the display or to the proximity of the indicated location to a point within the intersected selectable region. Dwell time may be continuous, discontinuous or dynamic (described below) for either or both subregions of the selectable region.

Selection in the above example is in response to a dwell event. A dwell event includes, but is not limited to, each of the following: (a) the durations of one or more periods of intersection of locations indicated by a movement related signal, a body member or a cursor (including any part of the cursor) and a selectable region equalling or exceeding a predetermined period; (b) a first  
5 quantity responsive to the durations of the periods referred to in (a) equalling or exceeding a predetermined quantity; (c) dwell event (a) or (b) followed by a location indicated by the movement related signal, the body member or the cursor no longer intersecting the intersected selectable region; and (d) dwell event (a) or (b) wherein the period of intersection required for selection of a selectable region increases in response to a non-intersection or a period of non-  
10 intersection of locations indicated by the movement related signal, the body member or the cursor and the selectable region ("dynamic dwell event"). The use of non-intersection or a period of non-intersection in determining the duration of a period of intersection required for selection is called dynamic dwell. Associated with each type of dwell event is an intersected selectable region. This is the selectable region intersected by the location indicated by the movement related signal, body  
15 member or cursor which triggers the dwell event by causing the period or the first quantity to equal or exceed the predetermined period or the predetermined quantity, respectively.

Selection may also be in response to a selection event. A selection event includes, but is not limited to: (a) a dwell event; (b) a switch operation at or near the time of an intersection of a  
20 location indicated by a movement related signal, a body member or a cursor and a selectable region; (c) an intersection of a location indicated by a movement related signal, a body member or a cursor and a selectable region; and (d) selection event (c) followed by a location indicated by the movement related signal, the body member or the cursor no longer intersecting the selectable region it previously intersected. Associated with each type of selection event is an intersected  
25 selectable region. This is the selectable region intersected by the location indicated by the movement related signal, body member or cursor. The fact that a selection event has occurred may be indicated to the operator, for example, visually by changing the cursor appearance or location, by changing location, size, shape, hue, brightness, contrast, tone, dithering, pattern, hatching, font or fill of an object on the surface, or by displaying a graphic or a point distinguishable from its  
30 immediate surroundings on a surface or removing a graphic or point distinguishable from its immediate surroundings from a surface; audibly by generating a sound or changing the pitch or volume of an extant sound; tactilely by changing the surface or temperature of a contact area or the pressure exerted by a contact area; or by other means. In the prototype, following selection, the hue of the visible subregion of the selected selectable region is changed from green to magenta.

As used herein, a cursor includes a temporary marking on a display which emphasizes to an operator, in an optical manner, a momentarily important location or object. As used herein, body member means any part of the body including, but not limited to, each of the following: the shoulder, arm, elbow, wrist, hand, finger, thumb, leg, knee, ankle, foot, toe, hip, trunk, neck, tongue, lip, eye and head. The received movement related signal includes, but is not limited to, a signal indicative of movement or from which movement can be derived, such as a plurality of relative or absolute positions or a difference between two relative or absolute positions. Movement related signal receiving means includes, but is not limited to, each of the following: (a) pointer interface circuitry found in a general purpose computer system; (b) one or more detectors operative to detect movement of a pointer; and (c) one or more detectors operative to detect movement of a body member of an operator. In the prototype, the movement related signal receiving includes electronic circuitry in the general purpose computer system (2218) operative to receive the movement related signal generated in part by the movement of the pointer (2202).

In the prototype subregions are displayed on the display (2112). However, other means for displaying may be substituted for the means used in the prototype, for example, a projector for projecting an image, a surface having a static display thereon, or other suitable means.

Resuming, now, with the example of Figure 17, and assuming that the operator has selected menu option "vort<space>x", the display is changed to that shown in Figure 18. In Figure 18, each of six selectable regions is now associated with a submenu option of the selected menu option "vort<space>x". Selectable region (0104/0106) is now associated with submenu option "<space>", selectable region (0108/0110) with submenu option "o", selectable region (0112/0114) with submenu option "t", selectable region (0124/0126) with submenu option "x", selectable region (0128/0130) with submenu option "v", and selectable region (0132/0134) with submenu option "r". Selectable regions (0116/0118) and (0120/0122) remains associated with the same menu options with which each was associated in Figure 17. The operator may now select one of these submenu options.

Assuming that the selected submenu option is one of v, o, r, t, x and space, the selected character, or a corresponding computer encoding of that character, may be input to an apparatus coupled to the general purpose computer system (2218 in Figure 15), or input to an application program (1208) executing on the general purpose computer system (2218) coupled to the display (2112). Inputting, as used herein, includes, but is not limited to, generating or passing signals

representative of the selected menu option along a path toward the destination apparatus or program. Preferably, the computer program displays at least some of its output in the circumscribed region (0150).

- 5 Given a display having eight selectable regions, an operator may, with a single selection indicate one of eight menu options, with two selections indicate one of up to 64 different menu options, with three selections indicate one of up to 256 menu options, etc. Each of these menu options may represent a sequence of one or more characters, a sequence of one or more data or control inputs to an application program (1208), or a control function for one or more devices or speech synthesizers
- 10 coupled to the general purpose computer system (2218). As used herein, a character includes a space, a control character as defined by the American National Standards Institute (ANSI) or the American Standard Code for Information Exchange (ASCII), and a letter from one of the Afrikaans, Albanian, Amharic, Arabic, Armenian, Assamese, Assyrian, Avar, Azerbaijani, Balinese, Bamara, Bantu, Bashkir, Basque, Bengali, Birhari, Bulgarian, Buluba-Lulua, Burmese,
- 15 Buryat, Byelorussian, Caddoan, Catalan, Chechen, Chikaranga, Chippewa, Choctaw, Church Slavik, Chuvash, Coptic, Cree, Croatian, Cyrillic, Czech, Dakota, Danish, Dari, Devanagari, Dutch, Dzongkha, English, Eskimo, Esperanto, Estonian, Ewe, Farsi, Fijian, Filipino, Finnish, Flemish, French, Fulani, Gaelic, Galician, Georgian, German, Greek, Gujarati, Gurmakhi, Harari, Hausa, Hawaiian, Hebrew, Hindi, Hiragana, Ibo, Icelandic, Indonesian, Irish, Iroquoian, Italian,
- 20 Kabardian, Kalmyk, Kannada, Kanuri, Kashmiri, Katakana, Kazakh, Khasi, Khmer, Kirghiz, Kishmiri, Komi, Kongo, Kurdish, Lao, Latin, Latvian, Lithuanian, Lu-Guanda, Macedonian, Magahi, Maithili, Makua, Malagasy, Malay, Malayalam, Maltese, Mandingo, Manipuri, Marathi, Masai, Mizo, Moldavian, Mongolian, Munda, Naga, Navaho, Nyanja, Nepalese, Norwegian, Oriya, Oromo, Ossetian, Pashto, Polish, Portugese, Punjabi, Rajasthani, Rhaeto-Romanic, Rumanian,
- 25 Russian, Samoan, Sangs, Serbian, Serbo-Croatian, Sinhalese, Sinhi, Sioux, Slovak, Slovenia, Spanish, Sundanese, Swahili, Swedish, Syriac, Tadjik, Tagalog, Tajik, Tamil, Tatar, Telugu, Thai, Tibetan, Turkish, Turkmen, Udmurt, Uighur, Ukrainian, Umbundu, Urdu, Uzbek, Vietnamese, Visayan, Welsh, Yakut, Yoruba and phonetic alphabets. As used herein, each of a character, ideograph, control input and control function includes a computer encoding of the same. As used
- 30 herein, a device includes, but is not limited to, each of a wheelchair, a household appliance, an appliance for use in an office, a workstation, a robot, and a computer peripheral. Thus, by selecting from a menu, the operator may, for example, increase the volume of an external speech synthesizer, or turn a wheelchair to the left.

The selectable regions organized as described above help an NMD operator make the menu selection he intends. Referring to Figure 17, suppose, for example, an NMD operator intends to move a pointer (2202) that is indicating point (0154) to indicate point (0156), a location in subregion (0130), but who is unable to quickly stop motion, so that the location indicated by the pointer (2202) moves from point (0154) past point (0156) to point (0158). Because point (0158) lies within the same selectable region (0128/0130) as the overshoot subregion (0130), dwelling at point (0158) operates to select the intended selectable region (0128/0130). Invisible subregions, in accordance with the Perimeter Menu aspect of the invention, may extend outward from the edge of the display (2112) to infinity. In such an embodiment, dwelling at point (0162) would operate to select selectable region (0128/0130). Preferably, invisible subregions extend a finite distance from the edge of the display (2112). In such an embodiment, dwelling at point (0162) would not operate to select selectable region (0128/0130). The sizes of the invisible subregions shown in Figures 17 and 18 are illustrative only. Preferably the size of each invisible subregion is large enough to encompass overshoot but small enough to avoid unintentional selections when the NMD operator turns to see someone or something.

The prototype utilizes the area outside the display to facilitate menu selection by a disabled operator. If an operator has impaired ability to maintain a steady position, he can point to a relatively large invisible subregion outside the display which is more forgiving of the operator's involuntary motion than the relatively small selectable regions on the display in conventional on-screen keyboards. Thus, the effective area of a selectable region is expanded beyond the region's visible subregion shown on a display. If an operator has impaired ability to stop motion he may, starting from the center of the screen, point to any selectable region. His impaired ability to stop will not impair his ability to select his intended target, assuming his directional control is relatively unimpaired, since, in the prototype, each selectable region is unbounded on its side furthest from the center of the display. Although the selectable regions of the prototype are large, only the visible subregion of each selectable region uses space on the display. Thus a large rectangular region remains available on the display for the output of an application program. The Perimeter Menu aspect of the invention is preferably implemented on a general purpose computer system. If the general purpose computer system is coupled to a speech synthesizer and the menu hierarchy allows the selection of letters and/or words, an operator having impaired speech may speak using the speech synthesizer. If a word processing or data entry application program is run on the general purpose computer system, the operator may enter words or data, respectively, for input to the application program. If the general purpose computer system is coupled to a devices capable of

executing commands and the menu hierarchy allows the selection of commands, a disabled operator may select and issue commands to control these devices.

Since the cognitive demand for scanning is greater than that for direct selection, the prototype  
5 places less cognitive demand on the operator than a scanning system for selecting options from a menu.

Figure 19 illustrates a display in accordance with an alternative embodiment of the Perimeter Menu aspect of the invention having eight selectable regions circumscribing a central region (6950)  
10 on the display.

Figure 20 illustrates a display in accordance with an embodiment of the Perimeter Menu aspect of the invention having twenty selectable regions circumscribing a central region (0806) on the display.

Figure 21 illustrates a display in accordance with an embodiment of the Perimeter Menu aspect of the invention having four selectable regions (0508), (0506), (0504) and (0502) circumscribing a central region (0510) on the display.

Figure 22 illustrates a display in accordance with an embodiment of the Perimeter Menu aspect of the invention having four selectable regions (4008), (4006), (4004) and (4002) with no space between them other than a circumscribed region (4010) on the display.

Figure 23 illustrates an apparatus in accordance with of another embodiment of the Perimeter Menu aspect of the invention. In Figure 23, region (3510) is located on interior display (3514) which is circumscribed by peripheral display (3512). Selectable regions (3508), (3535), (3504) and (3502) are located on the peripheral display (3512).

Figures 24 and 25 are each illustrations of a display and structures in accordance with another embodiment of the Perimeter Menu aspect of the invention. Figure 24 depicts ten selectable regions (6502), (6504), (6506), (6508), (6510), (6512), (6514), (6514), (6516), (6518), and (6520). Each selectable region is located on the display (2112) adjacent the edge of the display and associated respectively with a menu option. In Figure 24, the menu options are shown on their associated selectable region. Together the ten selectable region circumscribe region (6550) on the  
30

display. In response to only an intersection of a location indicated by a movement related signal and selectable region (6506), the display changes to that shown in Figure 25, on which are located ten selectable regions each located on the display (2112) adjacent the edge of the display, nine of the ten selectable regions associated respectively with a submenu option. Selectable region (6608) is not associated with a submenu option. Any submenu option may be selected by a selection event.

Figures 26 and 27 illustrate an apparatus in accordance with still another embodiment of the Perimeter Menu aspect of the invention. Figure 26 depicts a front view of the apparatus; Figure 27 a cut away view from the top of the apparatus. Figure 26 depicts detector area (0348 in Figure 27) on, in or below which are located a plurality of selectable regions (0304), (0306), (0308), (0310), (0312), (0314), (0316), (0318), (0320), (0322), (0324), (0326), (0328), (0330), (0332), (0334), (0336), (0338), (0340) and (0342). Adjacent the detector area (0348 in Figure 27) is a berm (0350 in both Figure 26 and 27) for confining a body member of the operator or a pointer controlled by the operator to the detector area (0348 in Figure 27).

Still another apparatus in accordance with the Perimeter Menu aspect of the invention is illustrated in Figure 28 which depicts a headrest for an operator using his head to indicate a location on a display. Figure 28 shows an irregularity (0703) on the surface (0701) of the headrest. The irregularity is in physical contact with the operator and tactilely indicates to him the position of his head. The tactile indication means may be concave, convex or both or may differ from the surface in temperature. For individuals having impaired ability to sense the position of a body member, e.g. the operator's head, the tactile input thus provided to the operator improves the operator's ability to sense the position of his head.

The prototype of the invention will now be described in detail and where the preferred mode of practicing the invention differs from the prototype, the preferred mode is described. The description is broken into several parts:

1. A brief overview of how a state table works.
2. A description of the operation of the events, state table and state processing used in the prototype.
3. A general description of each event and one example of the use of that event.
4. An example of state machine processing in the operation of the prototype.

The prototype implements the Perimeter Menu aspect of the invention as a state table. A state table is a tool for processing sequential inputs and is most easily understood by analogy. Imagine yourself in a room having a ticket window and three exits, each regulated by a turnstile. You collect a ticket at the ticket window which, when inserted into the appropriate turnstile, allows  
5 passage to a connecting room. The turnstile keeps the ticket. Any given ticket operates only one turnstile in a room, though different tickets may operate the same turnstile. You begin in a certain room, collect a ticket, insert it into the appropriate turnstile and pass to a connecting room, where you perform certain tasks associated with the new room. Then you collect another ticket from the ticket window in that room, insert the ticket into the appropriate turnstile in that room, pass to a  
10 connecting room, perform certain tasks associated with the new room, and so on.

The state table used in the prototype is depicted in Figures 29 and 30. Moving from the analogy above, the rooms are states represented by the rows of the state table; the tickets are events represented by the columns of the state table. Each entry in the state table represents a passage  
15 from one state to another. The tasks performed upon entry into a room correspond to the processing performed by the processor (2104) on entry to a new state ("state processing"). For example, state processing may cause a slight lightening of the color of a selectable region. Reentry into that state five times may successively lighten a selectable region five times.

20 In the prototype, each selectable region is directly controlled by one associated state machine. Each state machine directly controls only its associated selectable region. Each state machine includes data uniquely associated with its associated selectable region, the shared state table shown in Figures 29 and 30, and the shared code for state processing, described below. This embodiment means that the state machine associated with selectable region (1614) may be in state  
25 ST\_SELECTED while the state machine associated with selectable region (1602) is in state ST\_INITIAL. In the prototype, these separate states are reflected only in separate values for data uniquely associated with each state machine. Each state machine has a unique index.

The state table used in the prototype defines 18 states, composed of states zero through seventeen shown in Figures 29 and 30. State 1 (ST\_ERROR\_STATE in Figure 29) is not used. Preferably, it  
30 is omitted. In the prototype, the differences between the several state machines, for example, the state of a particular state machine at any given time, are confined to data structures associated with that state machine. The state machines share the same code and the same state table. In other words, returning to the ticket and turnstile analogy, there are multiple travelers each with his own

ticket (event) and his own baggage (data) moving from room to room in the same labyrinth. Each traveler's actions in each room usually affect only his own baggage.

In the prototype, there are two types of sequential inputs processed by the state table: external events and internal events. External events are generated outside the state table, for example, by the operator moving the pointer (2202) or by a timer expiring. Pointer movement may generate an event indicating that the operator has moved the cursor across the selectable region boundary from without the selectable region to within it. This event causes a transition from one state to another ("drives" a state machine to a new state). For example, assuming a state machine is in state ST\_CREST\_TIDE, row 6 in the state table shown in Figure 29, when an event EV\_CROSS\_OUT, column 4 of the state table, occurs. At the intersection of row 6 and column 4 is a 7. This represents the new state, row 7 of the state table, state ST\_SELECTED. Thus event EV\_CROSS\_OUT drives the state machine from state ST\_CREST\_TIDE to state ST\_SELECTED. On entry to the new state, the computer performs the state processing associated with the new state.

Internal events are generated during state processing to handle circumstances where a first state transition is made due to an external event and the processing associated with the new state determines that a second state transition is necessary. The first, external, event has already been used so a second, internal, event is generated by the state. For example, if the operator has a prolonged muscle spasm, common among individuals with CP, or loses his grip on a hand held pointing device, the cursor may sit without moving on a selectable region for a considerable period of time. It is desirable to detect this condition, move the cursor to the center of the screen so the operator can easily find the cursor, and reset all selectable regions to their initial color. Detection is accomplished with a timer. On timer expiration, a state machine transitions to state ST\_IDLE which centers the cursor. From there it is desirable to transition to state ST\_RESET which, among other processing, initializes selectable region color. The transition from state ST\_IDLE to state ST\_RESET is driven by an internal event, generated by state ST\_IDLE state processing.

Although the preferred embodiment uses only one state to perform certain state processing, that state processing may be equivalently performed in multiple states. Likewise, the state processing of multiple states of the described embodiment may be equivalently performed in a single state.

Although the prototype uses a state table to control the flow of program execution and to select one of a plurality of selectable regions, the same function may be equivalently performed using object

oriented software architecture, if-then-else statements or a combination of these. In particular, in accord with object oriented software architecture, each state machine may be equivalently represented as an instantiation of a selectable region class for processing inputs affecting a particular selectable region.

5

Although the described embodiment uses a single processor, state table and code for state processing for all the selectable regions, each of these may be duplicated. Alternate embodiments may include processors, electronic circuitry, state tables or code for state processing used for processing fewer than all the selectable regions or used to process certain selectable regions at one time and other selectable regions at other times.

10

In the prototype, each state machine processes events independently of all other state machines, though a state machine may send an event to another state machine. For example, when the operator selects a selectable region, the associated state machine sends the event EV\_RESET to all other state machines so that all selectable regions revert to their respective initial colors.

15

A single operator action may result in the issuance of different events to different state machines. For example, when the operator moves the cursor from without a selectable region to within it, EV\_DWELL is sent to the newly indicated state machine. EV\_MOVEMENT is sent to all other state machines.

20

Following is a general description of each event used in the prototype and an example of the use of each event. For all uses of each event, refer to the state table shown in Figures 29 and 30 which determines what state transition occurs from every state on occurrence of a given event.

25

The event EV\_RESET is an internal event which drives a state machine to its initial state. For example, when the operator has not moved the pointer (2202) for a predetermined period of time, event EV\_RESET is sent to all other selectable regions.

30

The event EV\_DECAY is an external event which indicates that the cursor hotspot does not intersect the selectable region associated with the state machine. EV\_DECAY is sent to a state machine periodically when the operator has positioned the cursor hotspot on a selectable region other than the selectable region associated with that state machine.

The event EV\_DWELL is an external event which indicates that the cursor hotspot intersects the selectable region associated with the state machine. EV\_DWELL is sent to a state machine periodically when the operator has positioned the cursor hotspot on the associated selectable region.

5

The event EV\_CROSS\_OUT is an external event which indicates that the cursor hotspot has moved from a location intersecting the selectable region associated with the state machine to a location not intersecting the selectable region. After the operator selects a selectable region, he must move the cursor hotspot out of the selectable region, generating EV\_CROSS\_OUT, before he can again select that selectable region.

10

The event EV\_STEP\_UP is an internal event which indicates that a selectable region's selection threshold has been satisfied.

15

The event EV\_MOVEMENT is an external event which indicates that the cursor hotspot has moved. If the cursor hotspot intersects a selectable region without moving for a predetermined period of time, a timeout occurs, causing all state machines to transition to the reset state. EV\_MOVEMENT drives the state machine out of the reset state.

20

The event EV\_IDLE\_TIMEOUT is an external event which indicates that the cursor hotspot has intersected a selectable region without moving for a predetermined period of time. EV\_IDLE\_TIMEOUT causes the state machine to move the cursor hotspot to the center of the display.

25

The event EV\_CEILING is an external event which indicates that the cursor hotspot intersects a selectable region and the color of the selectable region equals the selectable region color ceiling. If the locking feature is enabled, EV\_CEILING drives the state machine to the begin lock state where it displays the lock icon.

30

The null event, EV\_NULL, is a multi-purpose internal event used in a variety of situations to drive a state machine to another state. For example, after a timeout has been detected, EV\_IDLE\_TIMEOUT is generated and sent to the appropriate state machine driving it to the idle state, the receiving state machine sends itself EV\_NULL in order to drive itself to the reset state. The use of EV\_NULL here allows states to be simpler and the reset state to be reused.

The prototype uses eight partially delimited selectable regions. In the description below, the portion of each selectable region shown on the display is referred to as the visible subregion of the selectable region. The portion of each selectable region outside the display is referred to as the invisible subregion of the selectable region. Because the software driver (1202) confines the cursor hotspot to the Windows® cursor clipping rectangle, a rectangle on the display slightly smaller in area than the display, the access program (1206) of the prototype only reads hotspot cursor locations within the Windows® cursor clipping rectangle, even though the operator may in fact be pointing to a location outside the Windows® cursor clipping rectangle, e.g. within an invisible subregion. Thus the access program (1206) does not distinguish between two locations indicated by the operator, the first at a first location on the edge of the Windows® cursor clipping rectangle and the second outside the Windows® cursor clipping rectangle whose location is reported by the software driver (1202) to be the first location. For example, assuming that the operator moves the location indicated by the pointer (2202) to a location within invisible subregion (0104 in Figure 17), the software driver (1202) in the prototype reports the cursor hotspot location to be the closest point within the visible subregion (0106). Consequently, in the prototype, all invisible subregions are unbounded on their side furthest from and parallel to the edge of the display. Thus, in the prototype, point (0162) in Figure 17 lies within selectable region (0128/0130) since the rightmost side of selectable region (0128/0130) is unbounded.

The operation of the prototype will now be described using, as an example, the selection of a menu option associated with selectable region (0104/0106). First described are notation conventions used in the description, then initialization in the prototype, and then the example. The description refers to the procedures PocketFsm and CreateEvent. These procedures are listed in pseudo-code in Appendix I.

25

Notational conventions used in the description below:

1. pPocket-> indicates a set of data associated with a particular state machine, in this example, the state machine associated with selectable region (0104/0106).
2. pPocket->State indicates a particular item of data within the set of data associated with the state machine, in this case, the variable "State".

30

During initialization:

1. The Windows® cursor clipping rectangle is set so that most of the arrow cursor is always visible on the display.

2. The cursor, indicating on the display (2112) the location indicated by the movement related signal receiving means, is positioned at the center of the display.
3. All data associated with each state machine are initialized. The following variables are included in the set of data associated with each state machine. There are as many independent  
 5 copies of these variables as there are state machines. For each state machine the following variables are initialized as indicated.

	variable	initial value	meaning
	fInvert	FALSE	if TRUE, display the color complementary to that indicated by this selectable region's Color variable
10	State	ST_INITIAL	state of the state machine
	PreviousState	0	previous state of the state machine
	Color	0	RGB encoding of visible subregion color
	fPaint	FALSE	if TRUE, paint visible subregion on receipt of WM_PAINT message
15	InitialColor	RGB (0,32,0)	initial value corresponds to a dark green
	pLabel	initial menu option for the state machine's selectable region	indicates an element within the aLabel array, described below
20	Decrement	RGB (0,1,0)	value subtracted from Color on EV_DECAY
	Increment	RGB (0,4,0)	value added to Color on EV_DWELL
	Ceiling	RGB (0,255,0)	initial value corresponds to a very light, bright green
	CrestTide	RGB (0,143,0)	initial value corresponds to a light green
25	Lockspot.x	a point within the selectable region located two thirds of the length of the selectable region from the closest corner of the display	x coordinate of location for the display of the lock icon
30	Lockspot.y	a point within the selectable region	y coordinate of location for the display of the lock icon

- located two thirds of  
the length of the  
selectable region from  
the closest corner of  
the display
- 5  
fInterior TRUE for interior if TRUE, this is an interior region  
regions, otherwise of adjacent regions  
FALSE: used for  
the Intersection  
10 aspect of the invention
- iAdjacentPocket  
index of state machine associated  
with the adjacent region; used for  
the Intersection  
15 aspect of the invention
- first array of points  
boundaries of the  
visible subregion  
second array of points  
20 boundaries of the  
region; used for the Intersection  
aspect of the invention
- hRegion handle to Windows® region  
corresponding to the visible subregion;  
25 used for the Intersection  
aspect of the invention
4. aLabel, an array of data structures defining the menu and submenu options and the menu  
hierarchy, is initialized. For example, one of the elements of aLabel defines menu option  
30 "vort<space>x". This element includes fields which determine that this menu option is  
displayed horizontally starting at certain (x,y) coordinates, that on selection certain actions  
are to be taken, for example, outputting text to a speech synthesizer, and that on selection  
certain submenu options, in this example, "v", "o", "r", "t", "<space>" and "x", and related  
data are to be associated with certain state machines. In the prototype, this association is

accomplished by modifying pLabel in the set of data of the associated state machine to point to the aLabel element corresponding to the menu option to be associated with that state machine.

5. At least one window is created in the circumscribed region (0150) for the display of selected letters.
6. The state table is initialized to the values shown in Figures 29 and 30.
7. EV\_RESET is sent to each state machine by a procedure call of the form PocketFsm (pPocket, EV\_RESET). As an example, assume pPocket indicates the state machine associated with selectable region (0104/0106). Proceeding through the pseudo-code for the procedure PocketFsm listed in Appendix I, fInternalEvent is set to TRUE and consequently control passes into the while loop. fInternalEvent is now set to FALSE. The current state, pPocket->State, is stored in pPocket->PreviousState. Now a state transition is made. The current state, ST\_INITIAL, having a value of 2, and the current event, EV\_RESET, having a value of 1, are used as row and column indices respectively into the state table aPocketFsm shown in Figures 29 and 30, to determine the value of the new state of the state machine, in this example, the state machine associated with selectable region (0104/0106). aPocketFsm[2][1] equals 3. Thus the new state of the state machine is 3, the value of ST\_RESET. Control passes, via the switch statement, to the ST\_RESET case and ST\_RESET state processing is performed. The time of selectable region selection is set to the current time, the state machine's fInvert flag is set to FALSE and the value of the state machine's color variable, pPocket->Color, is compared to the state machine's initial color, pPocket->InitialColor. pPocket->Color was initialized to zero, which is not the value of pPocket->InitialColor. Consequently, pPocket->Color is set to pPocket->InitialColor and the flag pPocket->fPaint is set to TRUE. Upon reaching the break statement, control passes through the bottom of the switch statement and the value of pPocket->fPaint is tested. Since it is TRUE, the client area rectangle is invalidated. In the prototype, Windows® (1204) responds to invalidating the client rectangle by sending the access program (1206) a WM\_PAINT message. On receipt of a WM\_PAINT message, the access program (1206) redraws all selectable regions and any menu option located thereon for each state machines having pPocket->fPaint equal to TRUE. Thus, somewhat indirectly, visible subregion (0106) is drawn on the display (2112). Then control returns to Windows® (1204). The other seven state machines, each associated respectively with a selectable region, are similarly initialized so that each state machine transitions from ST\_INITIAL to ST\_RESET and draws its respective visible subregion and any menu option located thereon on the display (2112). The

display shown in Figure 17 now appears on the display (2112) of the computer system (2116).

8. A periodic timer, called the cursor polling timer, is set. This timer provides the access program (1206) with a WM\_TIMER message at frequent intervals, in the prototype every system clock tick which occurs approximately every 54 milliseconds. Following access program (1206) initialization, most state transitions are made on expiration of the cursor polling timer. The access program (1206) calls the procedure CreateEvent to determine the appropriate event for each state machine and to complete the event data structure addressed by pEvent accordingly, then repetitively calls the procedure PocketFsm for each state machine, passing the unique indicator for the state machine and the appropriate event for that state machine. Preferably, the cursor polling timer is more frequent so that color changes to visible subregions are smaller and more frequent, giving a smoother appearance to color change.

15 An example of the selection of selectable region (0104/0106) in accord with the Perimeter Menu aspect of the invention will now be described. Following initialization, assume that the operator now begins to move the pointer (2202). Every 54 milliseconds the cursor polling timer expires, causing Windows® (1204) to send a WM\_TIMER message to the access program (1206). Following receipt of WM\_TIMER, the access program (1206) calls the procedure CreateEvent.

20 The procedure CreateEvent, among other functions, determines whether the current cursor hotspot location lies within any selectable region. In this example, the operator is moving the cursor from its initial location in the center of the display toward selectable region (0104/0106), but since only 54 milliseconds have elapsed, the cursor hotspot has moved only slightly in that direction. The procedure CreateEvent determines that the cursor hotspot does not lie within any selectable region and that the cursor hotspot has not crossed out of a selectable region in the past 54 milliseconds.

25 Therefore, the procedure CreateEvent determines that each state machine should receive EV\_MOVEMENT. The procedure PocketFsm is called with the indicator for the state machine associated with selectable region (0104/0106) and with EV\_MOVEMENT. The event EV\_MOVEMENT drives this state machine from its current state, ST\_RESET, to ST\_EBB\_TIDE.

30 The pseudo-code for ST\_EBB\_TIDE in procedure PocketFsm is a break statement, indicating that no state specific action is taken at this time, other than the transition to ST\_EBB\_TIDE. Control returns to Windows® (1204).

Shortly before or shortly after the state machine associated with selectable region (0104/0106)

receives EV\_MOVEMENT, all other state machines each receive EV\_MOVEMENT and each makes the same transition from ST\_RESET to ST\_EBB\_TIDE.

Another 54 milliseconds elapses and again procedure PocketFsm is called, sending  
 5 EV\_MOVEMENT to the state machine associated with selectable region (0104/0106) and driving state machine from ST\_EBB\_TIDE to ST\_DECAY. Stepping through the pseudo-code for ST\_DECAY, the ST\_DECAY state sets pPocket->State to the value stored in pPocket->PreviousState and decrements pPocket->Color but not below the value of pPocket->InitialColor. pPocket->Color determines the color and brightness of visible subregion  
 10 (0106). Decrementing pPocket->Color results in a darkening of visible subregion (0106). Resuming with the pseudo-code for ST\_DECAY state processing, the ST\_DECAY state sets fInternalEvent to TRUE, and, in this case, sets Event to EV\_NULL. Following the break statement, the while fInternalEvent condition is true and another state transition occurs, using the value of pPocket->State which was set by ST\_DECAY state processing to ST\_EBB\_TIDE, the  
 15 previous state. The new state is found at aPocketFsm[ST\_EBB\_TIDE][EV\_NULL], which equals ST\_EBB\_TIDE. This state transition is unlike an ordinary state transition because the starting state is set by ST\_DECAY. All transitions from ST\_DECAY share this distinction. The state machine executes the code for the new state, ST\_EBB\_TIDE, which is simply a break statement. The procedure PocketFsm determines that fPaint is FALSE and exits. Control returns to Windows®  
 20 (1204).

Shortly before or shortly after the state machine associated with selectable region (0104/0106) receives EV\_MOVEMENT, all other state machines each receive EV\_MOVEMENT and each makes the same transitions from ST\_EBB\_TIDE to ST\_DECAY to ST\_EBB\_TIDE.

25 Every 54 milliseconds this scenario is repeated for each state machine until the operator moves the cursor hotspot to a point within selectable region (0104/0106). At this time the procedure CreateEvent determines that there is an active selectable region, specifically selectable region (0104/0106), and that consequently EV\_DWELL should be sent to the associated state machine.  
 30 The procedure PocketFsm is called with the indicator for the state machine associated with selectable region (0104/0106) and the event EV\_DWELL. EV\_DWELL drives this state machine from ST\_EBB\_TIDE to ST\_ENTRY. Following the pseudo-code for ST\_ENTRY state processing shown in PocketFsm pseudo-code, fInternalEvent is set to TRUE and Event is set to EV\_NULL, resulting in another state transition to aPocketFsm[ST\_ENTRY][EV\_NULL], which equals

ST\_LOW\_TIDE.

The pseudo-code for ST\_LOW\_TIDE is only a break statement, so there is no state specific action for ST\_LOW\_TIDE other than entry into this state. fPaint is FALSE so the selectable region is not redrawn. Control returns to Windows® (1204).

Shortly before or shortly after the state machine associated with selectable region (0104/0106) receives EV\_DWELL, all other state machines each receive EV\_MOVEMENT and each makes the same transitions from ST\_EBB\_TIDE to ST\_DECAY to ST\_EBB\_TIDE.

Another 54 milliseconds elapses. The procedure CreateEvent determines that the state machine associated with selectable region (0104/0106) should receive EV\_MOVEMENT, which drives it from ST\_LOW\_TIDE to ST\_DWELL. Stepping through the pseudo-code for ST\_DWELL, the ST\_DWELL state sets pPocket->State to the value stored in pPocket->PreviousState, increments pPocket->Color by pPocket->Increment, but not above the value of pPocket->Ceiling, sets pPocket->fPaint to TRUE, sets fInternalEvent to TRUE, and, in this case, sets Event to EV\_NULL. Following the break statement, the while fInternalEvent condition is true and another state transition occurs. The new state is found at aPocketFsm[ST\_LOW\_TIDE][EV\_NULL], which equals ST\_LOW\_TIDE. This path is unlike an ordinary state transition because the starting state is set by ST\_DWELL. All transitions from ST\_DWELL share this distinction. The state machine executes the code for the new state, ST\_LOW\_TIDE, which is simply a break statement. The procedure PocketFsm determines that fPaint is TRUE, invalidates the client rectangle and exits. As a result of invalidating the client rectangle, Windows® (1204) sends a WM\_PAINT message to the access program (1206). On receipt of WM\_PAINT, the access program (1204) checks the value of fPaint for each state machine, and if TRUE, sets fPaint to FALSE and redraws the visible subregion of the selectable region associated with that state machine and any menu option located thereon. The color of the redrawn visible subregion is determined by the value of the Color variable for that state machine. After redrawing, control returns to Windows® (1204).

Shortly before or shortly after the state machine associated with selectable region (0104/0106) receives EV\_DWELL, all other state machines each receive EV\_MOVEMENT and each makes the state transitions from ST\_EBB\_TIDE to ST\_DECAY to ST\_EBB\_TIDE.

Assuming the operator maintains the cursor hotspot in the selectable region (0104/0106), the state

machine associated with selectable region (0104/0106) cycles repetitively through the state transitions from ST\_LOW\_TIDE to ST\_DWELL to ST\_LOW\_TIDE, driven by the cursor polling timer. With each transition to ST\_DWELL, visible subregion (0106) is brightened a bit. The polling timer interval is short enough and the increment to pPocket->Color is small enough that

5 visible subregion (0106) appears to gradually brighten although in fact it progresses rapidly through a series of discrete brightness levels. With each iteration through ST\_DWELL, pPocket->Color is incremented.

Assuming that the operator maintains the cursor hotspot on selectable region (0104/0106),

10 pPocket->Color will eventually equal or exceed pPocket->CrestTide, a variable set at initialization time and not changed thereafter. At this time, Event is set to EV\_STEP\_UP, driving a transition to aPocketFsm[ST\_LOW\_TIDE][EV\_STEP\_UP], which equals ST\_SELECTED. The state processing for ST\_SELECTED provides the operator with an audible indication that a selection has just been made, takes the action appropriate upon selection of this selectable region, including

15 selecting the menu option associated with the selected selectable region. In this example, the access program (1206) does not generate output to another program or device at this time.

ST\_SELECTED next sets pPocket->fInvert to TRUE, and, if appropriate, changes the menu options associated with various selectable regions. In this example, selectable region (0104/0106) is now associated with menu option "<space>", selectable region (0108/0110) with menu option

20 "o", selectable region (0112/0114) with menu option "t", selectable region (0124/0126) with menu option "x", selectable region (0128/0130) with menu option "v", and selectable region (0132/0134) with menu option "r". Selectable regions (0116/0118) and (0120/0122) remains associated with the same menu options with which they were associated in Figure 17. fPaint is set to TRUE for the state machines associated with the selectable regions having changed menu options.

25 ST\_SELECTED next sets Event to EV\_NULL and fInternalEvent to TRUE. The state machine now makes the transition to aPocketFsm[ST\_SELECTED\_TIDE][EV\_NULL], which equals ST\_CREST\_TIDE. There is no state specific action for ST\_CREST\_TIDE other than entry into this state. The pseudo-code for ST\_CREST\_TIDE is only a break statement. Control returns to Windows® (1204).

30 When the access program (1206) later receives the WM\_PAINT message resulting from the invalidating of the client rectangle, the setting of fInvert to TRUE causes the visible subregion (0106) to be drawn in the color complementary to the value then indicated by pPocket->Color. The setting of fPaint to TRUE for all selectable regions associated with changed menu options

causes those selectable regions and the menu options thereon to be redrawn. The display shown in Figure 18 now appears on the display (2112) of the computer system (2116).

Assuming the operator maintains the cursor hotspot in the selectable region (0104/0106), the state machine associated with selectable region (0104/0106) cycles repetitively through the state transitions from ST\_CREST\_TIDE to ST\_DWELL to ST\_CREST\_TIDE, driven by the cursor polling timer. With each transition to ST\_DWELL, visible subregion (0106) is brightened a bit, though it is now magenta, the complement of green. The polling timer interval is short enough and the increment to pPocket->Color is small enough that visible subregion (0106) appears to gradually brighten although in fact it progresses rapidly through a series of discrete brightness levels. With each iteration through ST\_DWELL, pPocket->Color is incremented. Assuming that the operator maintains the cursor hotspot on selectable region (0104/0106), pPocket->Color will eventually equal pPocket->Ceiling, a variable set at initialization time and not changed thereafter.

Assuming that the operator now moves the cursor so that the hotspot is located outside selectable region (0104/0106), CreateEvent generates the EV\_CROSS\_OUT for the state machine associated with selectable region (0104/0106), driving the state machine to aPocketFsm[ST\_CREST\_TIDE][EV\_CROSS\_OUT], which equals ST\_SELECT\_AND\_OUT. The state processing for ST\_SELECT\_AND\_OUT sends EV\_RESET and then EV\_MOVEMENT to all state machines, driving each of them from their current state to ST\_RESET and then to ST\_EBB\_TIDE. For each state machine, the transition ST\_RESET and then to ST\_EBB\_TIDE results in actions previously described for those states, except that, unlike before, the value of pPocket->Color for the state machine associated with selectable region (0104/0106) does not equal the value of pPocket->InitialColor for the state machine associated with selectable region (0104/0106). Consequently, pPocket->Color is set to pPocket->InitialColor and fPaint is set to TRUE, subsequently causing visible subregion (0106) to be redrawn in its initial color. Control returns to Windows® (1204).

The prototype continues to sample cursor location at 54 millisecond intervals, determine the appropriate event for each state machine and send that event each state machine, causing state transitions in each state machine according to the state table shown in Figures 29 and 30.

Assuming that the operator next selects selectable region (0108/0110), the state processing in ST\_SELECTED displays the selection, the letter "o", in the circumscribed region (0150), and associates the menu options shown in Figure 17 with their respective selectable regions. The

display shown in Figure 17 appears on the display (2112) of the computer system (2116).

#### B. Confinement

5 The preferred embodiment of the Confinement aspect of the invention will now be described in detail from a functional perspective using an example illustrated in Figure 31. In Figure 31, 20 selectable regions, e.g. (1704), (1708) and (1714), are depicted on display (2112). Each of the selectable regions is located on the display (2112) adjacent an edge of the display, and the selectable regions together circumscribe a region (1702) on the display. The top and left edges of  
10 the Windows® cursor clipping rectangle (1750) lie on the top and left edges, respectively, of the display (2112). The bottom and right edges of the Windows® cursor clipping rectangle (1750) lie on the display parallel to and slightly indented from the bottom and right edges, respectively, of the display. A confining polygon is delimited on the display. The boundary of the confining polygon, starting from the upper right corner of the Windows® cursor clipping rectangle, follows the top  
15 edge of the Windows® cursor clipping rectangle to the left until it reaches region (1732), where the boundary follows the side of region (1732) down, to the left, and back up to the top edge of the Windows® cursor clipping rectangle. The boundary continues left along the top edge of the Windows® cursor clipping rectangle until it reaches region (1734), where the boundary follows the side of region (1734) down, to the left, and back up to the top edge of the Windows® cursor  
20 clipping rectangle. The boundary continues left along the top edge of the Windows® cursor clipping rectangle to the upper left corner and then turns down along the left edge of the Windows® cursor clipping rectangle until it reaches region (1736), where the boundary follows the side of region (1736) to the right, down, and to the left to the left edge of the Windows® cursor clipping rectangle. The boundary of the confining polygon continues in this fashion around to the  
25 upper right corner of the Windows® cursor clipping rectangle. The confining polygon thus includes all the area of the Windows® cursor clipping rectangle except for the regions (1732), (1734), (1736), (1738), (1740), (1742), (1744), and (1746). An operator controlling a pointer indicating successive locations with respect to the display and attempting to select a target  
30 Windows® cursor clipping rectangle. In the preferred embodiment of the Confinement aspect of the invention, the cursor (1724) is confined to the confining polygon. The preferred embodiment is responsive to an intersection of the cursor hotspot and any one selectable region so that an overshoot selectable region may be selected by click or by dwell without moving the location presently indicated by the pointer to a location in the overshoot selectable region. Thus, the preferred

embodiment of the Confinement aspect of the invention allows an operator with impaired ability to stop motion to maintain the cursor more easily on a selectable region, and so select the intended selectable region, than do conventional user interface systems.

5 A selectable region having a single side abutting a confining polygon prevents cursor movement only beyond the abutting side. However, NMD operators who drift may drift in more than one direction. Assume that a certain NMD operator tends to drift both up and to the left and that he is attempting to select selectable region (1704). If he moves the cursor into that selectable region his upward drift will be confined; the drift will not move the cursor beyond the confining polygon.

10 However, the cursor will move to the left, since, in the preferred embodiment of the Confinement aspect of the invention, movement in this direction is not affected by the confining polygon, and consequently the cursor may move into selectable region (1708), the selectable region to the left of selectable region (1704). NMD operators having this type of drift may be assisted in selecting by confining corners. For example, such an operator, attempting to select selectable region (1704)

15 could move the cursor to location (1706) in selectable region (1704). As the operator drifts to the left, he can compensate by moving the pointer to the right. Assuming the operator lacks fine motor control, he may overcompensate and indicate a location to the right of the Windows® cursor clipping rectangle (1750). However, since the cursor is confined to the confining polygon, the cursor remains in the intended selectable region.

20

Confining corners facilitate the selection process for some NMD operators. The preferred embodiment of the Confinement aspect of the invention creates a corner or virtual corner in each selectable region. A virtual corner is a corner of a selectable region formed by the intersection of two sides of a selectable region both of which abut a confining polygon. For example, corner

25 (1710) in selectable region (1708) abuts the confining polygon both along the top edge of the Windows® cursor clipping rectangle and along the right side of region (1732). If an NMD operator drifts from selectable region (1708) to the left into region (1732), the cursor remains in selectable region (1708). Thus, drift to the left does not move the cursor out of selectable region (1732). An operator trying to select selectable region (1708) may overcompensate for drift to the

30 right by moving the pointer to indicate a location in region (1732).

Figure 32 illustrates a display in accordance with an alternative embodiment of the Confinement aspect of the invention. Figure 32 depicts 16 selectable regions, e.g. selectable region (0602), on a display (2112), the selectable regions together at least partially circumscribing region (0660) on the

display. Circumscribed region (0660) intersects four selectable regions, (0604), (0608), (0610), and (0612). Selectable region (0608) includes virtual corner (0652). The confining polygon includes all the area of the Windows® cursor clipping rectangle except for regions (0632), (0634), (0636), (0638), (0640), (0642), (0644), and (0646).

5

Figure 33 illustrates a display and structures in accordance with another embodiment of the Confinement aspect of the invention. Figure 33 depicts 20 selectable regions, e.g. selectable region (0918), on a display (2112), the selectable regions together at least partially circumscribing region (0902) on the display. The confining polygon includes all the area of the Windows® cursor clipping rectangle except for regions (0906), (0908), (0910), and (0904).

10

The preferred embodiment of the Confinement aspect of the invention will now be described in detail from an implementation perspective. Preferably, the Confinement aspect is implemented by modifications to the access program (1206) described in the detailed description of the Perimeter Menu aspect of the invention. The modifications required are: (1) define 20 state machines and 20 respectively associated selectable regions located as shown in Figure 31; (2) at initialization time, create a Windows® region corresponding to the confining polygon described above in the functional description of the preferred embodiment of the Confinement aspect of the invention; and (3) modify the procedure CreateEvent so that before generating an EV\_CROSS\_OUT event, CreateEvent determines whether the current hotspot cursor location intersects the confining polygon, and, if not, set the Windows® hotspot cursor location to the previous hotspot cursor location and transfers control to the code at the beginning of the CreateEvent procedure which gets the current cursor hotspot location from Windows®. If the current hotspot cursor location intersects the confining polygon, CreateEvent takes the same action as in the access program (1206).

15

20

25

### C. Dwell

The preferred embodiment of the Dwell aspect of the invention will now be described in detail from a functional and implementation perspective. The prototype implements dynamic dwell. The effect of dwelling on a selectable region and its implementation have been described in the detailed description of the Perimeter Menu aspect of the invention. Now the effect and implementation of moving the cursor hotspot off a selectable region will be described.

30

Referring now to Figure 17, assuming that the state machine associated with the selectable region (0104/0106) is in state ST\_LOW\_TIDE, that pPocket->Color has been incremented above its initial value, that the cursor hotspot intersected selectable region (0104/0106) at the last expiration of the cursor polling timer, and that the operator initiates movement of the cursor hotspot to the right  
 5 from selectable region (0104/0106) toward selectable region (0132/0134) so that, when the cursor polling timer next expires, the cursor hotspot is located in area (0150) between visible subregions (0106) and (0134), the procedure CreateEvent determines that the state machine associated with selectable region (0104/0106) should receive EV\_CROSS\_OUT, which drives it from ST\_LOW\_TIDE to ST\_LOW\_TIDE. The state processing for ST\_LOW\_TIDE has already been  
 10 described in the detailed description of the Perimeter Menu aspect of the invention.

Assuming that the operator continues to move the cursor hotspot toward selectable region (0132/0134), on the next expiration of the cursor polling timer, the procedure CreateEvent determines that the state machine associated with selectable region (0104/0106) should receive  
 15 EV\_MOVEMENT, which drives it from ST\_LOW\_TIDE to ST\_DECAY. Stepping through the pseudo-code for ST\_DECAY, the ST\_DECAY state sets pPocket->State to the value stored in pPocket->PreviousState, decrements pPocket->Color by pPocket->Decrement, but not below the value of pPocket->InitialColor, sets pPocket->fPaint to TRUE, sets fInternalEvent to TRUE, and, in this case, sets Event to EV\_NULL. Following the break statement, the while fInternalEvent  
 20 condition is true and another state transition occurs. The new state is found at aPocketFsm[ST\_LOW\_TIDE][EV\_NULL], which equals ST\_LOW\_TIDE. This path is unlike an ordinary state transition because the starting state is set by ST\_DECAY. All transitions from ST\_DECAY share this distinction. The state machine executes the code for the new state, ST\_LOW\_TIDE, which is simply a break statement. The procedure PocketFsm determines that  
 25 fPaint is TRUE, invalidates the client rectangle and exits. As a result of invalidating the client rectangle, Windows® (1204) sends a WM\_PAINT message to the access program (1206). On receipt of WM\_PAINT, the access program (1204) checks the value of fPaint for each state machine, and if TRUE, sets fPaint to FALSE and redraws the visible subregion of the selectable region associated with that state machine and any menu option located thereon. The color of the  
 30 redrawn visible subregion is determined by the value of the Color variable for that state machine. After redrawing, control returns to Windows® (1204).

If the movement of the cursor hotspot pause between successive samplings of its location, the procedure Create Event will determine that not EV\_MOVEMENT, but EV\_DECAY, should be

sent to the state machine associated with selectable region (0104/0106). Like EV\_DECAY, EV\_MOVEMENT drives the state machine associated with selectable region (0104/0106) to ST\_DECAY. The same state processing as described above for ST\_DECAY takes place, including the transition back to ST\_LOW\_TIDE.

5

Assuming the operator maintains the cursor hotspot in area (0150), the state machine associated with selectable region (0104/0106) cycles repetitively through the state transitions from ST\_LOW\_TIDE to ST\_DECAY to ST\_LOW\_TIDE, driven by the cursor polling timer. With each transition to ST\_DECAY, visible subregion (0106) is darkened a bit. The polling timer interval is short enough and the decrement to pPocket->Color is small enough that visible subregion (0106) appears to gradually darken although in fact it progresses rapidly through a series of discrete brightness levels. With each iteration through ST\_DECAY, pPocket->Color is decremented until pPocket->Color reaches pPocket->InitialColor.

10

When the cursor hotspot reaches selectable region (0132/0134), the procedure CreateEvent determines that the state machine associated with selectable region (0104/0106) should receive EV\_DECAY, continuing the repetitively cycling through from ST\_LOW\_TIDE to ST\_DECAY to ST\_LOW\_TIDE, driven by the cursor polling timer. Driven by the same polling timer, the procedure CreateEvent determines that the state machine associated with selectable region (0132/0134) should receive EV\_DWELL, driving this state machine through the state transitions described in the detailed description of the Perimeter Menu aspect of the invention.

20

If the operator moves the cursor hotspot from selectable region (0132/0134) back to selectable region (0104/0106), the procedure CreateEvent determines that the state machine associated with selectable region (0104/0106) should receive EV\_DWELL, driving this state machine through the state transitions described in the detailed description of the Perimeter Menu aspect of the invention.

25

In the prototype, the selectable regions are shown on a display (2112). Alternatively, the selectable regions may appear on a static display, or they may be projected on a surface.

30

In the prototype, the brightness of a visible subregion at any time indicates the progress of the selection of the selectable region including the visible subregion. A brightness close to the initial brightness indicates that a relatively long period of dwelling on this selectable region is required for selection. A brightness close to the brightness just prior to selection indicates that relatively

short period of dwelling on this selectable region is required for selection. However, means for indicating an intersection of the location indicated by the movement related signal and a selectable region, or the duration of a period of such an intersection includes, but is not limited to, a change in cursor appearance or location, a change in location, size, shape, hue, brightness, contrast, tone, dithering, pattern, hatching, font or fill of an object on the surface, a display of or change in a graphic on the surface or the removal of a graphic from the surface, a generation of a sound or a change in the pitch or volume of an extant sound, a change in the temperature or surface of a contact area, the pressure exerted by a contact area, or frequency of contact by a contact area, or other suitable means. Any of these indications may be continuous or frequent.

Although dwell is implemented in the prototype using a data value, specifically pPocket->Color, it may be implemented using a signal, for example, voltage or current, varying in response to the intersection and subsequent non-intersection of a location indicated by a pointer and a selectable region. For example, a selectable region may include a detector and coupled electronics or electrical circuitry operative to increase the voltage level of a capacitor. Once elevated, the voltage level may decrease over time. Upon reaching a predetermined threshold, the voltage level may trigger selection.

The prototype allows an operator to make selections by dwell more efficiently than in conventional systems. In the prototype, the brightness of a visible subregion indicates the dwell time required for selection. A practiced operator may accurately estimate when he may plan his next pointer movement, when he may begin moving the pointer and may determine when a bit more exertion will select a selectable region and when it will not. Thus a disabled operator who is fatigued by computer access and can maintain a pointer in a steady position for only brief periods, may optimize his energy expenditure, for example, exerting himself to maintain the cursor on a certain selectable region only when doing so will quickly select the selectable region.

The prototype may increase the independence of a disabled individual by allowing him to control devices such as a TV, thermostat and other household appliances. As stated earlier, the Perimeter Menu aspect of the invention may be implemented on a general purpose computer system. If the general purpose computer system is coupled to a devices capable of executing commands and the menu hierarchy allows the selection of commands, a disabled operator may select and issue commands to control these devices.

Figure 34 illustrates a display in accordance with of an embodiment of the Dwell aspect of the invention having 20 selectable regions (3101), (3103), (3105), (3107), (3109), (3111), (3115), (3117), (3119), (3121), (3125), (3127), (3129), (3131), (3133), (3135), (3139), (3141), (3143), and (3145) circumscribing a surface (3151) having an indicating region (3147) thereon.

5

Figure 35 illustrates an apparatus in accordance with of an embodiment of the Dwell aspect of the invention having 20 selectable regions circumscribing a surface, each selectable region associated respectively with an indicating region adjacent its associated selectable region. Selectable region (3101) is associated with indicating region (3201), selectable region (3103) with indicating region (3203), etc.

10

Figure 36 illustrates an apparatus in accordance with of an embodiment of the Dwell aspect of the invention having 20 detectors circumscribing an aperture (3350), each detector associated respectively with an indicator intersecting its associated detector, e.g. detector (3301) is associated with indicator (3303).

15

Figure 37 illustrates an apparatus in accordance with of an embodiment of the Dwell aspect of the invention having 24 selectable regions arranged in a grid of four rows and six columns, each selectable region associated respectively with an indicating region intersecting its associated selectable region. For example, selectable region (3402) is associated with indicating region (3401).

20

Figure 38 illustrates a display in accordance with of an embodiment of the Dwell aspect of the invention having a plurality of detectors, (2501), (2503), (2505), etc., arranged in a grid. Each detector is associated respectively with an indicator intersecting its associated detector., e.g. detector (2501) is associated with indicator (2502). Each detector is also associated respectively with an order entry item which may be selected by dwell. For example, detector (2501) is associated with a hamburger. Pointer (2512) (not drawn to scale) emits energy detectable by the detectors. Pointer (2512) may be housed in stationary housing (2514) (not drawn to scale).

25

30

Means for determining the difference between two data items or signals and means for totaling two or more data items or signals may each include a processing unit programmed to calculate this difference or total. Alternatively, the difference or total may be determined by electronic, mechanical, optical, or other suitable means.

The two step procedure described earlier for operating conventional menu-driven data entry and order entry systems incorporating pointing at intended selections may be simplified to a single step in accordance with the Dwell aspect of the invention. Referring now to Figure 38, the operator points pointer (2512) at an order entry item. The item brightens responsive to the signals falling on the associated detector, indicating to the operator which order entry item he is dwelling on and his dwell time on that order entry item. When his dwell time equals or exceeds the selection threshold, the order entry item is selected. The operation of such a system is intuitive and may be learned or relearned by pointing and dwelling. No surface is required, unlike a standard mouse. Additionally, an operator seated in the driver's seat of a vehicle is probably right-handed and may be making selections with his left hand, the hand closest to the window in a left-hand drive vehicle. Pointing and maintaining a pointer in a steady position requires less coordination than pointing and clicking.

#### D. Path Directness

The Path Directness aspect of the invention includes several aspects, hereinafter "subaspects", called Facilitated Dwell, Direction and Intersection, Direction, Appraisal and Drift Attenuation. The preferred embodiment and certain alternative embodiments of each of these subaspects will now be described.

According to the Facilitated Dwell subaspect of the invention, the duration of the dwell period required for selection ("selection threshold period") of a menu option associated with a selectable region varies with the directness of the cursor's path to that selectable region. The preferred embodiment of the Facilitated Dwell subaspect of the invention will now be described in detail from a functional perspective using an example illustrated in Figure 39. In Figure 39 on display (2112) are defined corridors (2302), (2304), (2306), (2308), (2310), (2312) and (2314) lying between the previously selected selectable region (2318) and, respectively, selectable regions (2342), (2344), (2346), (2348), (2350), (2352) and (2354). Each selectable region is associated respectively with a selection threshold period. Each cursor location in a cursor path, for example cursor path (2322), may slightly decrease one or more the selection threshold periods, except for the selection threshold period associated with the previously selected selectable region, selectable region (2318) in this example. The effect of a cursor location depends, in the preferred embodiment, on whether that cursor location intersects one of the corridors. If it does, as for example location (2324) intersects corridor (2308), then the selection threshold period associated with the selectable region to which the intersected corridor leads, (2348) in this example, is

decreased, preferably to a limit of approximately 20% of the initial value of the selection threshold period so that some period of intersection of the cursor and the intended selectable region is still required for selection. A changed selection threshold period is preferably indicated by a change in the brightness of the selectable region associated with the changed selection threshold period.

5 Thus, when the operator moves the cursor within a corridor, the selectable region associated with the corridor brightens, indicating both the target selectable region the system believes the cursor is headed toward and the changed selection threshold period. When the operator moves the cursor outside a corridor the cursor had previously intersected, the selectable region associated with the previously intersected corridor darkens in accord with the dynamic dwell aspect of the invention.  
10 indicating both that the system no longer believes the cursor is headed toward that selectable region and the changed selection threshold period. Reducing the selection threshold period facilitates selection of dwell-selectable regions without unduly increasing the likelihood of erroneous selections, since cursor locations within a corridor evidence the operator's intention to select the selectable region associated with the corridor.

15 Preferably, corridors are hidden from view, but they may be shown on the display or shown only at certain times or under certain conditions. Corridors may have fixed boundaries, depending on which selectable region has been selected, or their boundaries may be determined when a starting location, for example, cursor location (2316) in Figure 39, is known. Corridor  
20 shape, size, number and position about the associated selectable region may vary, as illustrated by the alternative embodiments shown in Figures 40 and 41. Where corridors overlap, a cursor location intersecting two or more corridors may be defined to be in a cursor path toward zero, one or more selectable regions associated with the intersected corridors.

25 The intersection of a cursor location and a corridor is but one means of identifying which one of a plurality of selectable regions is most nearly along a cursor path. A cursor path may be indicated by an intersection of a cursor location and a predetermined region, e.g. a corridor, by a cursor location and a movement related signal from which may be derived a second location, or by two or more successive cursor locations. As used herein, successive locations include a plurality of  
30 locations distributed in time. Successive location may be, but need not be, consecutive. Given a location and a movement related signal or two locations, an intention to select a particular selectable region may be inferred, for example, by extrapolation, and the selection thresholds associated with either or both the intended or unintended selectable regions modified accordingly. As an example, assume successive cursor locations are periodically stored in a ring buffer and the

magnitude of the angle between two line segments, the first between the oldest cursor location in the ring buffer and a predetermined point in the selectable region, and the second between the oldest cursor location in the ring buffer and the current cursor location, is determined. The selectable region associated with the smallest of these angles may be considered to be the  
5 selectable region most nearly along the cursor path indicated by the first line segment.

An alternative means of identifying which one of a plurality of selectable region is most nearly along a cursor path is to determine the ratio of the number cursor locations indicating a selectable region to the total cursor locations in the cursor path.

10

Figure 42 illustrates still another alternative means for identifying which one of a plurality of selectable regions is most nearly along a cursor path. Figure 42 shows line (2410) from starting cursor location (2406) to ending cursor location (2408) just within selectable region (2404). Line (2410) is the most direct path between these two points. In this example, the actual path traveled  
15 by the cursor between these two points is path (2412). The ending cursor location (2408) is known before the selection threshold period associated with selectable region (2404) is modified.

Identification may be made by measuring or approximating the area within region (2414) bounded by line (2410) and cursor path (2412). The smaller the area, the more direct the cursor path.

Alternatively, identification may be made by storing a sampling among successive cursor locations  
20 along a cursor path and, in response to the cursor intersecting a selectable region, the selectable region most nearly along the cursor path may be identified at one or more sampled points along the cursor path. The identification may be based upon a plurality of cursor locations or upon a single cursor location and a movement related signal. Alternatively, identification may be made by measuring and comparing the number of times a cursor path diverges from a predetermined path  
25 toward the intersected selectable region and/or the degree of divergence of a cursor path from a predetermined path toward the intersected selectable region.

Another apparatus in accord with the Path Directness aspect of the invention is illustrated in Figure 34. In this Figure, selectable regions (3101), (3103), (3105), (3107), (3109), (3111), (3115),  
30 (3117), (3119), (3121), (3125), (3127), (3129), (3131), (3133), (3135), (3139), (3141), (3143) and (3145) circumscribe area (3151). Area (3151) and optionally the selectable regions include detectors for sensing radiant energy emitted from a pointer (2202) coupled to a body member of the operator. A computer coupled to the detectors determines which selectable region is most nearly along the path indicated by the body member of the operator. Responsive to the indicated path, the

embodiment may facilitate the selection of one of the selectable regions by reducing a selection threshold, may select a selectable region upon intersection of the point indicated by the pointer (2202) and a selectable region, or may select a particular selectable region in advance of intersection of the point indicated by the pointer (2202) and the particular selectable region.

5

A move direction of a body member of an operator may be determined in any way that a cursor path may be determined, including sampling among data indicative of position of the body member. In determining move direction of a body member, data indicative of body member positions may serve the same function as cursor locations in indicating a path toward a selectable region. Position indicating means, used, for example, in indicating a position of the body member, includes each of the means for indicating that a selection event has occurred.

10

As an alternative to decreasing a selection threshold period, an embodiment may include a plurality of selection thresholds, each associated respectively with a selectable region. One or more of the selection thresholds may be increased when the direction of cursor movement does not indicate a path toward the associated selectable region.

15

Means for indicating which one of the plurality of selectable regions is most nearly along the cursor path includes each of the means for indicating an intersection of the location indicated by the movement related signal and a selectable region.

20

According to the Direction and Intersection subaspect of the invention, the selection threshold period is completely satisfied in response to a cursor path to a particular selectable region, so that when the cursor intersects the particular selectable region, that region is selected. Preferably, the selection threshold period is completely satisfied in response to a measure of directness of a cursor path to a particular selectable region equalling or exceeding a predetermined measure of directness. In circumstances where the measured directness is less than the predetermined measure, a dwell period is required for selection of the particular selectable region.

25

According to the Direction subaspect of the invention, a selectable region is selected in response to a cursor path to that selectable region, in advance of an intersection of the cursor and that selectable region. Preferably, the selectable region is selected in response to a measure of directness of a cursor path to a particular selectable region equalling or exceeding a predetermined measure of directness. In circumstances where the measured directness is less than the predetermined

30

measure, a dwell period is required for selection of the particular selectable region.

According to the Appraisal subaspect of the invention, the directness of a cursor path to a selectable region is measured. Preferably, the means for measuring the directness of a cursor path includes each of the means for identifying which one of a plurality of selectable regions is most nearly along a cursor path. Thus, the particular means for identifying which one of a plurality of selectable regions is most nearly along a cursor path which best correlates with an operator's intended target selectable region may be identified.

As earlier described, some NMD operators have relatively unimpaired directional control, despite having other movement disorders. The Facilitated Dwell, Direction and Intersection, and Direction subaspects of the Path Directness aspect of the invention utilize that capability for computer access. Specifically, the ability of an operator to move a cursor in a direct path toward a selectable region is used to facilitate selection of that selectable region. The selectable region is selected more quickly than in conventional systems utilizing selection by dwell, increasing operator productivity. In addition, when selectable regions are located in accordance with the Perimeter Menu aspect of the invention, a cursor path toward a selectable region is often unambiguous, since usually there is only one selectable region along a cursor path, and a large rectangular area on the display is available for the output of an application program and is not obstructed by the menu. In certain embodiments in accordance with the Facilitated Dwell, Direction and Intersection, and Direction subaspects of the Path Directness aspect of the invention, the operator may receive an indication of which selectable region the system believes the operator is moving the cursor toward. The operator may adjust the cursor path in response to this feedback and thus move the pointer more accurately. Additionally, in embodiments in accordance with both the Facilitated Dwell subaspect of the Path Directness aspect of the invention and the Dwell aspect of the invention, the operator may receive an indication of the dwell time required to select the selectable region most nearly along the cursor path as the required dwell time changes in response to the cursor path.

The preferred embodiment of the Drift Attenuation subaspect of the invention will now be described in detail from a functional perspective using an example illustrated in Figure 43. Figure 43 depicts the upper right corner of a display (2112) having two selectable regions (0434) and (0430) thereon. Assuming, for purposes of this example, that a movement related signal indicates the path shown from point (0402) to point (0404) ("first segment") at a relatively high velocity and from point (0404) to point (0408) ("second segment") at a relatively low velocity. The path of the

first segment is relatively direct, the path of the second segment, relatively meandering. During receipt of the movement related signal for the first segment, the cursor preferably tracks the exact path indicated by the movement related signal. During receipt of the movement related signal for the second segment, the movement of the cursor is attenuated, preferably so that the cursor does not leave selectable region (0434) until it is selected.

Many NMD operators are unable to cleanly stop movement of a body member, resulting in a relatively slow or meandering path being indicated by the movement related signal. According to the Drift Attenuation subaspect of the invention, drift, that is, unintentional movement, indicated by the movement related signal following intentional movement is distinguished from the intentional movement, and cursor movement responsive to the drift is attenuated relative to cursor movement responsive to intentional movement. Thus unintentional movements of NMD operators are filtered so that the cursor is displayed closer to the location intended by the operator and drifting of the cursor into a nearby, but unintended, selectable region, is avoided, resulting in fewer errors due to unintended selections.

The preferred embodiment of each subaspect of the Path Directness aspect of the invention will now be described in detail from an implementation perspective. Preferably, the Facilitated Dwell subaspect is implemented by modifications to the access program (1206) described in the detailed description of the Perimeter Menu aspect of the invention. The modifications required are: (1) Additional state processing should be added to ST\_SELECTED to create a Windows® region in the shape of a corridor starting a predetermined distance from the selected selectable region to each of the other selectable regions; (2) The event data structure should be expanded to accommodate an event for a selectable region along a cursor path; (3) The procedure CreateEvent should be changed so that, before setting an event to EV\_DECAY or EV\_MOVEMENT, a test is made for the intersection of the cursor hotspot and each corridor, and, on finding such an intersection, a new event, EV\_CORRIDOR, is stored in the event data structure indicated by pEvent for the selectable region associated with the intersected corridor; (4) A column should be added to the state table so that each state which in the prototype may receive either EV\_MOVEMENT or EV\_DECAY will on receipt of EV\_CORRIDOR drive that state machine to ST\_CORRIDOR; (5) An additional variable, CorridorIncrement, preferably having an initial value one half the value of Increment, should be added the set of data associated with each state machine; and (6) A new state, ST\_CORRIDOR, should be added to the procedure PocketFsm. The pseudo-code for state processing in ST\_CORRIDOR follows:

```

case ST_CORRIDOR:
    /* set state to previous state */
    /* in preparation for the next */
    /* state transition */
5      set pPocket->State to pPocket->PreviousState
      increment pPocket->Color by
      pPocket->CorridorIncrement, but not above
      pPocket->InitialColor plus 80% of the
      difference between pPocket->CrestTide and
10     pPocket->InitialColor
      if pPocket->Color was changed
          set pPocket->fPaint to TRUE
          set fInternalEvent to TRUE
          set Event to EV_NULL
15     break

```

An example of the selection of selectable region (2346) in accord with the preferred embodiment of the Facilitated Dwell subaspect of the invention will now be described with reference to Figure 39, assuming that the prototype has been modified as described, that the operator has just selected

20 selectable region (2318), that all state machines are in state ST\_RESET, and that the operator moves the cursor hotspot from a location inside selectable region (2318) to location (2316), a location just outside selectable region (2318). On receipt of the next WM\_TIMER message, procedure PocketFsm is called with the indicator for the state machine associated with selectable region (2318) and with event EV\_CROSS\_OUT. Event EV\_CROSS\_OUT drives this state

25 machine from its current state, ST\_RESET, to ST\_EBB\_TIDE. The pseudo-code for ST\_EBB\_TIDE in procedure PocketFsm is a break statement, indicating that no state specific action is taken at this time, other than the transition to ST\_EBB\_TIDE. Control returns to Windows® (1204).

30 Shortly before or shortly after the state machine associated with selectable region (2318) receives EV\_CROSS\_OUT all other state machines each receive EV\_MOVEMENT and each makes the transition from ST\_RESET to ST\_EBB\_TIDE.

Assume that the operator moves the cursor hotspot along path (2322) toward location (2332), a

location outside all corridors, and then the next WM\_TIMER message is received. All state machines receive EV\_MOVEMENT and are driven from ST\_EBB\_TIDE to ST\_DECAY to ST\_EBB\_TIDE. The state processing associated with these states has been described in the description of the Perimeter Menu aspect of the invention.

5

Assuming that the operator moves the cursor hotspot along path (2322), the transition from ST\_EBB\_TIDE to ST\_DECAY to ST\_EBB\_TIDE is repeated every 54 milliseconds for each state machine until the operator moves the cursor hotspot beyond location (2332). At this time the procedure CreateEvent determines that the cursor hotspot intersects corridor (2308) and that

10 consequently EV\_CORRIDOR should be sent to the state machine associated with selectable region (2348). EV\_CORRIDOR drives this state machine from ST\_EBB\_TIDE to ST\_CORRIDOR. Stepping through the pseudo-code for ST\_CORRIDOR, the ST\_CORRIDOR state sets pPocket->State to the value stored in pPocket->PreviousState, increments pPocket->Color by pPocket->CorridorIncrement, but not above pPocket->InitialColor plus 80% of

15 the difference between pPocket->CrestTide and pPocket->InitialColor, sets pPocket->fPaint to TRUE, sets fInternalEvent to TRUE, and sets Event to EV\_NULL. Following the break statement, the while fInternalEvent condition is true and another state transition occurs. The new state is found at aPocketFsm[ST\_EBB\_TIDE][EV\_NULL], which equals ST\_EBB\_TIDE. This path is unlike an ordinary state transition because the starting state is set by ST\_CORRIDOR. All

20 transitions from ST\_CORRIDOR share this distinction. The state machine executes the code for the new state, ST\_EBB\_TIDE, which is simply a break statement. The procedure PocketFsm determines that fPaint is TRUE, invalidates the client rectangle and exits. As a result of invalidating the client rectangle, Windows® (1204) sends a WM\_PAINT message to the access program (1206). On receipt of WM\_PAINT, the access program (1204) checks the value of fPaint

25 for each state machine, and if TRUE, sets fPaint to FALSE and redraws the visible subregion of the selectable region associated with that state machine and any menu option located thereon. The color of the redrawn visible subregion is determined by the value of the Color variable for that state machine. The incremented value of pPocket->Color results in a slight brightening of selectable region (2348) and reduces the difference between pPocket->Color and pPocket->CrestTide,

30 corresponding to the dwell period required to select the associated selectable region. After redrawing, control returns to Windows® (1204).

Shortly before or shortly after the state machine associated with selectable region (2348) receives EV\_CORRIDOR, all other state machines each receive EV\_MOVEMENT and each makes the

state transitions from ST\_EBB\_TIDE to ST\_DECAY to ST\_EBB\_TIDE.

- This scenario is repeated at 54 millisecond intervals while the cursor hotspot travels along path (2322) to location (2326), a location intersecting corridor (2308). Between this location (2326) and location (2328), a location intersecting corridor (2306), along path (2322), the procedure CreateEvent determines that all state machines should receive EV\_MOVEMENT, driving each of them from their current state to ST\_DECAY and back to their current state. As described in the example in the detailed description of the Perimeter Menu aspect of the invention, ST\_DECAY state processing darkens the selectable region associated with the state machine, but not below a predetermined brightness represented by the variable InitialColor. Thus selectable region (2348) darkens when the cursor hotspot no longer intersects corridor (2308). From location (2328) to location (2330), the procedure CreateEvent determines that the state machine associated with selectable region (2346) should received EV\_CORRIDOR and all other state machines EV\_MOVEMENT. Consequently, selectable region (2346) gradually brightens up to a ceiling represented by pPocket->InitialColor plus 80% of the difference between pPocket->CrestTide and pPocket->InitialColor. The duration of dwell time required for selection of selectable region (2346) is thus reduced to approximately 20% of the dwell period required without Facilitated Dwell.
- Preferably, the Direction and Intersection subaspect of the invention is implemented by making the changes to the prototype described for the Facilitated Dwell subaspect, except that, in incrementing pPocket->Color in ST\_CORRIDOR, the upper limit for pPocket->Color in ST\_CORRIDOR state processing is pPocket->CrestTide minus pPocket->Increment. Assuming these changes, a selectable region whose associated Color variable is at this upper limit is selected during processing of the WM\_TIMER message immediately following the intersection of the cursor hotspot and the selectable region.

- Preferably, the Direction subaspect of the invention is implemented by making the changes to the prototype described for the Direction and Intersection subaspect of the invention, except that (1) the corridors are narrow, as illustrated in Figure 40; and (2) the pseudo-code for state processing in ST\_CORRIDOR is as follows:

```
case ST_CORRIDOR:
    /* set state to previous state */
```

```

/* in preparation for the next */
/* state transition */
set pPocket->State to pPocket->PreviousState
increment pPocket->Color by
5 pPocket->CorridorIncrement but not above
pPocket->Ceiling
if pPocket->Color was changed
    set pPocket->fPaint to TRUE
set fInternalEvent to TRUE
10 if pPocket->Color was changed from a value
    below
    pPocket->CrestTide to a value greater than or
    equal to
    pPocket->CrestTide
15     set Event to EV_STEP_UP
    else
        set Event to EV_NULL
    break

```

20 State ST\_CORRIDOR may now generate the internal event EV\_STEP\_UP, as state ST\_DWELL does in the detailed description of the Perimeter Menu aspect of the invention. A state machine in state ST\_EBB\_TIDE having a Color variable equal to or exceeding the CrestTide variable, will transition via PocketFsm[ST\_EBB\_TIDE][EV\_STEP\_UP] to ST\_SELECTED, and perform the ST\_SELECTED state processing described in the detailed description of the Perimeter Menu

25 aspect of the invention.

Preferably, the Appraisal subaspect of the invention is implemented by making the changes to the prototype described for the Facilitated Dwell subaspect, except that (1) the corridors are visible on the display (2112), (2) one of the selectable regions is designated to be the target selectable region

30 and this is indicated to the operator, (3) cursor locations are stored in memory (2106), and (4) following an intersection of the cursor hotspot and the target or selection of a selectable region other than the target, path directness is measured in accordance with the stored cursor locations.

The preferred embodiment of the Drift Attenuation aspect of the invention will now be described in

detail from an implementation perspective. Preferably, the Drift Attenuation aspect is implemented by modifications to the access program (1206) described in the detailed description of the Perimeter Menu aspect of the invention, modified as described above in the description of the implementation of the preferred embodiment of the Facilitated Dwell subaspect of the invention and further modified as follows: (1) add two booleans to the data set associated with each state machine, one called fDirectPath, the other fAttenuateDrift, and initialize each of them in all state machines to FALSE; (2) in both ST\_DECAY and ST\_CORRIDOR, set both pPocket->fDirectPath and pPocket->fAttenuateDrift to FALSE; (3) append to ST\_ENTRY state processing corresponding to the following pseudo-code:

10

```
if pPocket->Color equals or exceeds
(pPocket->InitialColor + (0.5 * (pPocket->CrestTide -
pPocket->InitialColor)))
    set pPocket->fDirectPath to TRUE
```

15

(4) append to ST\_DWELL state processing corresponding to the following pseudo-code:

20

```
if the present cursor position intersects the edge of
the Windows® cursor clipping rectangle and
pPocket->fDirectPath is TRUE
    set pPocket->fAttenuateDrift to TRUE
if pPocket->fAttenuateDrift is TRUE
    store the difference in each of the x and y
    coordinates ("delta") between consecutive cursor
    locations in a circular buffer accommodating the
    last ten deltas, overwriting the oldest delta with
    the newest delta
    if ten deltas have been accumulated
        calculate the average acceleration indicated
        by the last ten deltas
        if the average acceleration is negative
            set the cursor at the location one half
            the distance between the current cursor
            location and the previous cursor location
```

25

30

display the cursor at this new cursor  
location

#### E. Intersection

5

The preferred embodiment of the Intersection aspect of the invention will now be described in detail from a functional perspective using an example depicted in Figures 44, 45, 46. Figure 44 shows the display (2112) of a general purpose computer system (2218 in Figure 15) to which is coupled a pointer (2202). Eight regions are delimited with respect to the display (2112) and together circumscribe region (2650) on the display (2112). Four of these regions, (2602), (2612), (2622), and (2632), are entirely on the display (2112). Each of the other four regions respectively includes both a visible subregion ((2606), (2616), (2626), and (2636)) on the display (2112) and an invisible subregion ((2604), (2614), (2624), and (2634)) adjacent and outside the display (2112). Assume, for example, that the pointer is indicating location (2656) on the display (2112) and that the operator moves the pointer so that the location indicated by the pointer first intersects one of the regions at location (2652) in region (2612). Upon this intersection, the display changes to that shown in Figure 45. Figure 45 depicts a selectable region consisting of the union of invisible subregion (2714) and visible subregion (2716), hereinafter referred to as selectable region (2714/2716). Selectable region (2714/2712) is associated with menu option "sumac". In the preferred embodiment, the operator may select menu option "sumac" by dwelling on any part of the selectable region for the selection threshold period. Assuming, for example, that instead of moving the pointer from a position indicating location (2656) to location (2652), the operator instead moves the pointer so that the location indicated by the pointer first enters one of the regions at location (2654) in region (2614/2616). Upon this intersection, the display changes to that shown in Figure 46. Figure 46 depicts a selectable region consisting of the union of invisible subregion (2814) and visible subregion (2816), hereinafter referred to as selectable region (2814/2816). Selectable region (2814/2816) is associated with menu option "vort<space>x". In the preferred embodiment, the operator may select menu option "vort<space>x" by dwelling on any part of the selectable region for the selection threshold period.

30

In the preferred embodiment, each of the other seven regions shown in Figure 44 is associated with a selectable region and each selectable region is associated with a menu option. The menu options shown in Figure 44, in addition to "sumac" and "vort<space>x" are "wizen", "backspace", "words", "talk", "ldhbfk" and "ypgqj". The operator may select the menu option associated with any one of

the selectable regions by moving the location indicated by the pointer from circumscribed region (2650) into the region associated with the selectable region and then dwelling on the selectable region for the selection threshold period. Each selectable region preferably includes all the area of its associated region.

5

An operator having impaired ability to maintain a body member in a steady position but who can control the point at which the location indicated by a body member enters a region may, in accord with the Intersection aspect of the invention, use his relatively unimpaired motor capability to selectively enlarge a selectable region or determine which of two or more selectable regions will occupy a predetermined area, thus making it easier for him to select. If the general purpose computer system of the preferred embodiment is coupled to a speech synthesizer and the menu options are letters or words, an operator with impaired speech may select or spell words and speak them.

Figures 47 and 48 illustrate the upper right corner of a display in accordance with an alternative embodiment of the Intersection aspect of the invention. Figure 47 depicts the upper right corner of a display (2112) of a computer system (2116) having thereon two regions, (1404) and (1402), each associated respectively with a selectable region, each selectable region associated respectively with menu options "bdfhkl" and "<space>cmnrst". The selectable region associated with region (1402) includes all of region (1402). The selectable region associated with region (1404) includes all of region (1404) plus area (1406) between region (1404) and the right edge of the display (2112). Assuming the operator uses a pointer to indicate a location on the display and that the location to first intersect the union of regions (1402) and (1404) intersects region (1402), the display remains as shown in Figure 47. Dwelling in area (1406) operates to select the menu option "<space>cmnrst". If instead the location to first intersect the union of regions (1402) and (1404) intersects region (1404), the display changes to that shown in Figure 48. Dwelling in area (1406) then operates to select the menu option "bdfhkl".

The preferred embodiment of the Intersection aspect will now be described in detail from an implementation perspective. The Intersection aspect is preferably implemented by modifications to the access program (1206) described above in the detailed description of the Perimeter Menu aspect of the invention. The modifications are: (1) add a row to the state table aPocketFsm at row index 18 for a new state, ST\_EXIT and initialize the value of aPocketFsm[ST\_EXIT][EV\_NULL] to 4, the value of ST\_LOW\_TIDE; (2) at initialization time, change

aPocketFsm[ST\_LOW\_TIDE][EV\_CROSS\_OUT] to 18, the value of ST\_EXIT; (3) at initialization time for each state machine, (a) if the visible subregion associated with the state machine does not abut the edge of the display, set fInterior to TRUE, otherwise set fInterior to FALSE; (b) initialize iAdjacentPocket to the index of the state machine associated with the adjacent region. For example, assuming the index of the state machine associated with region (2614/2616) in Figure 44 is 2 and the index of the state machine associated with region (2612) in Figure 44 is 3, iAdjacentPocket in the data set associated with the state machine associated with region (2614/2616) is initialized to 3 and iAdjacentPocket in the data set associated with the state machine associated with region (2612) is initialized to 2; (c) initialize the second array of points to define the boundaries of the region associated with the selectable region associated with each state machine, for example, region (2612), and initialize the first array of points to define the boundaries of the visible subregion of the selectable region associated with the state machine, for example, visible subregion (2712); (4) remove creation of Windows® regions corresponding to visible subregions from the access program (1206) initialization; (5) append to ST\_ENTRY state processing corresponding to the following pseudo-code:

```

if pPocket->fInterior equals TRUE
    if pPocket->hRegion is not NULL
        delete the Windows® region having the handle
        pPocket->hRegion
    create a Windows® region having the boundaries
    defined by the second array of points associated
    with this state machine and set pPocket->hRegion
    to the handle to this region
    set pPocket->fPaint to TRUE
    send EV_RESET to all state machines except this one
    and the state machine having the index
    pPocket->iAdjacentPocket
    set pAdjacentPocket to point to the data set
    associated with the state machine having the index
    pPocket->iAdjacentPocket
    delete the Windows® region having the handle
    pAdjacentPocket->hRegion
    set pAdjacentPocket->hRegion to NULL

```

set pAdjacentPocket->fPaint to TRUE

(4) append to ST\_RESET state processing corresponding to the following pseudo-code:

```

5         if pPocket->hRegion is not NULL
            delete the Windows® region having the handle
              pPocket->hRegion
            create a Windows® region having the boundaries defined
              by the second array of points associated with this
10         state machine and set pPocket->hRegion to the handle
              to this region

```

An example of the selection of selectable region in accord with the Intersection aspect of the invention will now be described with reference to Figures 44 and 45. Following initialization,

15 assume that the operator moves the pointer (2202) from a position indicating location (2656) toward location (2652) in Figure 44. At the next expiration of the cursor polling timer, the procedure CreateEvent sends an EV\_MOVEMENT event to the state machine associated with the selectable region associated with the menu option "sumac". The event EV\_MOVEMENT drives this state machine from its current state, ST\_RESET, to ST\_EBB\_TIDE. The pseudo-code for

20 ST\_EBB\_TIDE in procedure PocketFsm is a break statement, indicating that no state specific action is taken at this time, other than the transition to ST\_EBB\_TIDE. Control returns to Windows® (1204). At the expiration of the cursor polling timer after the location indicated by the pointer reaches location (2652), the procedure CreateEvent sends event EV\_DWELL to the state machine associated with the selectable region associated with the menu option "sumac".

25 EV\_DWELL drives this state machine from ST\_EBB\_TIDE to ST\_ENTRY. Following the pseudo-code for ST\_ENTRY state processing shown above and in the Procedure PocketFsm, fInternalEvent is set to TRUE, Event is set to EV\_NULL, the Windows® region corresponding to region (2612), ie. the Windows® region having the handle pPocket->hRegion, is deleted and a new Windows® region having the boundaries indicated in the first array of points, ie. visible subregion

30 (2712) in Figure 45, is created and the handle stored in pPocket->hRegion. pPocket->fPaint is set to TRUE, EV\_RESET is sent to state machines associated with regions other than (2612) and (2614/2616). Data in the data set associated with the adjacent region (2614/2616) is now modified. The Windows® region corresponding to region (2614/2616) is deleted, hRegion for the state machine associated with that region is set to NULL and fPaint associated with that state machine is

set to TRUE. The event EV\_NULL drives the state machine associated with selectable region (2714/2712) to ST\_LOW\_TIDE. The pseudo-code for ST\_LOW\_TIDE is only a break statement, so there is no state specific action for ST\_LOW\_TIDE other than entry into this state. pPocket-fPaint is TRUE so the client rectangle is invalidated, resulting in the redrawing of Windows® regions associated with state machines having fPaint equal to TRUE so that the display (2112) appears as shown in Figure 45. Control returns to Windows® (1204).

Dwelling at any location within selectable region (2714/2712) now causes the procedure CreateEvent to send EV\_DWELL to the state machine associated with this selectable region. Selection of this selectable region proceeds as described above in the detailed description of the Perimeter Menu aspect of the invention.

Assuming the operator moves the location indicated by the pointer out of selectable region (2714/2712) prior to selection, the procedure CreateEvent sends the event EV\_CROSS\_OUT to the state machine associate with that selectable region, driving it to ST\_EXIT. The state processing for ST\_EXIT causes the display (2112) to change to that shown in Figure 44.

#### F. Alignment

The embodiment of the Alignment aspect of the invention as implemented in the prototype will now be described in detail from a functional and implementation perspective using an example depicted in Figures 49, 50, and 51. Each of these Figures depicts the upper right corner of a display (2112) having two visible subregions on the display. In these Figures, no subregions outside the display (2112) are shown. Alignment is achieved in several steps and requires operator interaction with the apparatus. For purposes of this example, assume that Figure 49 depicts the upper right corner of the display (2112), that an operator, fitted with a head pointer, desires to keep the cursor on the display directly in his line of sight and that the location indicated by the pointer is presently 15 degrees to the right of the location of the arrow cursor (1802). The operator now dwells on selectable region (1834) for an predetermined period ("the lock threshold") which preferably is significantly greater than the selection threshold period. The apparatus responds to this extended dwell period by changing the display to that shown in Figure 49. The arrow cursor is removed from the display and the lock icon (1902) is displayed in a predetermined location of the intersected selectable region ("lockspot") on the display. The lock icon remains on the lockspot for a predetermined period ("the lock period"); it does not move responsive to the operator's head

movement. While the lock icon is displayed, the operator turns his head, bringing his line of sight into alignment with the lockspot. At the expiration of the lock period, the apparatus changes the display to that shown in Figure 51. The lock icon is erased and the arrow cursor appears in the lockspot, which is where the operator is now looking. The arrow cursor moves in response to the operator's head movement.

An operator who loses alignment between location indicated by his pointer and the cursor may thus initiate an alignment sequence, and then, by moving his head or other body member when the prototype indicates he should do so by displaying the lock icon, regain alignment. That the lock icon is displayed indicates to the operator that he can align his head or other body member. The position of the lock icon indicates to the operator the location on the display with which he should align his head or other body member. This is the location where the arrow cursor will appear at the expiration of the lock period.

The Alignment aspect will now be described in detail from an implementation perspective as implemented in the prototype. The Alignment aspect of the invention is implemented an integral part of the state machine described in the detailed description of the Perimeter Menu aspect of the invention, using the same state machines and initialization, with the exception that aPocketFsm[ST\_CREST\_TIDE][EV\_CEILING] is changed from 9, the value of ST\_DWELL, to 14, the value of ST\_BEGIN\_LOCK. The operator initiates the alignment process by moving the cursor so that the cursor hotspot intersects a selectable region. As an example, Figure 49 shows the arrow cursor (1802) intersecting selectable region (1834). The operator then dwells on the selectable region for the lock threshold, preferably at least one second greater than the selection threshold period. This operator action causes the state machine associated with the intersected selectable region to reach state ST\_CREST\_TIDE. On receipt of the first WM\_TIMER message following entry into state ST\_CREST\_TIDE, the procedure CreateEvent creates event EV\_CEILING, which drives the state machine from state ST\_CREST\_TIDE to state ST\_BEGIN\_LOCK. The state processing within state ST\_BEGIN\_LOCK beeps, sets the system cursor location to the selectable region's lockspot, sets the system cursor to null erasing the arrow cursor, displays a the lock icon (1902 in Figure 50) on the selectable region's lockspot and initializes the global variable iLockCursor to the number of expirations of the cursor polling timer corresponding to the period of time the cursor will be locked (the "lock period") configured by the operator, preferably two seconds, and control is returned to Windows® (1204). Following the next expiration of the cursor polling timer, the procedure CreateEvent may generate an event

EV\_DECAY, EV\_DWELL, EV\_CROSS\_OUT, EV\_MOVEMENT or EV\_CEILING. Each of these events drives the state machine from state ST\_BEGIN\_LOCK to state ST\_LOCK. Within state ST\_LOCK the system cursor is moved to the selectable region's lockspot and iLockCursor is decremented. Then it is determined whether iLockCursor equals zero. If not, control returns to

5 Windows® (1204) for another iteration through ST\_LOCK. During the lock period, the system cursor is moved to the lockspot upon every expiration of the cursor polling timer, thus inhibiting movement of the cursor from the lockspot so that, during the lock period, the operator may move the location indicated by the pointer while the lock icon remains on or very close to the selectable region's lockspot. When, eventually, iLockCursor is decremented to zero, the global Event is set to

10 EV\_NULL and fInternalEvent is set to TRUE so that another state transition occurs immediately. This transition drives the state machine from state ST\_LOCK to state ST\_END\_LOCK. Within state ST\_END\_LOCK, the lock icon is erased, Windows® (1204) is directed to display the arrow cursor (2002) at the lockspot, as shown in Figure 51, the fPaint flag associated with the intersected selectable region is set to TRUE so that the selectable region will be drawn, restoring the

15 background behind the erased lock icon. Assuming the cursor hotspot remains on the selectable region for another 54 milliseconds, CreateEvent generates EV\_DWELL, which drives the state machine to ST\_DISCARD. Referring to the pseudo-code in PocketFsm, ST\_DISCARD state processing sets State to PreviousState, returning the state machine to ST\_END\_LOCK and in effect, discarding the last event. Following the expiration of the cursor polling timer after the

20 operator moves the cursor out of the selectable region it presently intersects, the procedure CreateEvent generates an event EV\_CROSS\_OUT which drives the state machine from state ST\_END\_LOCK to state ST\_SELECT\_AND\_OUT. The access program (1206) performs the state processing for state ST\_SELECT\_AND\_OUT and subsequent states as previously described in the description of the Perimeter Menu aspect of the invention.

25

In the prototype, the operator may initiate alignment by depressing any character key on the keyboard. On receipt of a WM\_CHAR message from Windows® (1204), the access program (1206) removes the arrow cursor from the display and displays the lock icon at a predetermined location on the display. In the prototype, the predetermined location is the center of the display

30 (2112). After a predetermined period, two seconds in the prototype, the lock cursor icon is erased and the arrow cursor displayed at the predetermined location.

In the prototype, the cursor is automatically centered if the cursor hotspot does not move for two minutes. Lack of movement of the cursor hotspot is detected in the procedure CreateEvent, which

generates the event EV\_IDLE\_TIMEOUT for all state machines. The state processing of each state machine on receipt of EV\_IDLE\_TIMEOUT depends upon its current state. State machines in states ST\_INITIAL and ST\_RESET stay in those states. State machines in all other states in which an external event can be received are driven to ST\_IDLE. Referring to the pseudo-code in

5 PocketFsm, ST\_IDLE state processing moves the cursor to the center of the display, sets fInternalEvent to TRUE and sets Event to EV\_NULL. PocketFsm[ST\_IDLE][NULL] equals 3, the value of ST\_RESET. The access program (1206) performs the state processing for the ST\_RESET and subsequent states as described in the description of the Perimeter aspect of the invention.

10 G. Length Order

The preferred embodiment of the Length Order aspect of the invention will now be described in detail from a functional and implementation perspective using an example depicted in Figure 52 and described in the detailed description of the Location Indication aspect of the invention.

15 Assume, for purposes of this example, that the operator has previously selected the letter "s". In the preferred embodiment, the string "s" is passed from the access program (1206 in Figure 16) via the Windows® Dynamic Data Exchange ("DDE") interface to a database program (1210 in Figure 16), preferably the FoxPro for Windows® version 2.6 program, available from Microsoft Corporation, Redmond, Washington, USA. The FoxPro program looks up the record having the

20 index "s" in a database composed of 26 letters, one for each letter of the alphabet. Each record includes one field for a letter of the alphabet and 12 fields containing the 12 most frequently used English words beginning with that letter. The 12 words in the record are ordered primarily by length, determined by the number of letters in each word, and secondarily by alphabetic order. The FoxPro program returns these 12 words to the access program (1206) and these are displayed on

25 the display (2112) as named menu options. The twelve named menu options, ordered as described and depicted in Figure 52, are "so", "say", "she", "said", "show", "some", "such", "state", "school", "social", "service", and "student". Preferably, only the root form of inflected forms of words which can be created through available suffixes ("root word") may be displayed as named menu options, so that the limited number of available menu options in combination with the apparatus'

30 capability to add suffixes offers a large number of inflected forms.

Words which may be named menu options in the same menu may be ordered by any suitable method. Preferably ordering is done by an ordering program operating on a corpus of text or speech including text or speech produced by individuals whose age, sex, geographic location and

disability are the same as or similar to that of the operator. The ordering program determines the frequency of use of root words in the corpus, selects the twelve most common root words, beginning with every possible combination of one, two and three letters, and stores them in three FoxPro databases for one, two and three letter word beginnings respectively, the words in each record ordered as described above. Ordering the words prior to a request minimizes the delay between the operator's selection of a letter or letters and the display of the named menu options. Preferably, the ordering program also creates a database of records for root words beginning with four or more letters. Each record includes the words and its frequency of use in the corpus. When the operator selects four or more letters consecutively, the access program (1206) requests via DDE that the FoxPro program (1210) look up words starting with four or more letters in the database for words beginning with four or more letters, select the 12 most frequently used words matching the selected letters, order them as described above, and return them to the access program (1206).

An operator searching named menu options for a desired menu option may start his search in the area on the display most likely to contain the desired menu option. Upon comparison of the length of the desired menu option to a displayed menu option, the operator may determine whether to continue his search from the displayed menu option toward the front of the list or toward the rear of the list, or to jump to another displayed menu option in the list. Further, he may make this determination more quickly than if the displayed menu options were sorted conventionally. The reduced menu option search time increases the operator's productivity with respect to conventional menu interfaces.

#### H. Location Indication

The preferred embodiment of the Location Indication aspect of the invention will now be described in detail from a functional perspective using an example depicted in Figure 52. Figure 52 shows the display (2112) of a general purpose computer system (2218 in Figure 15) having thereon eight selectable regions, each associated respectively with a menu option. Each of the eight selectable regions consists of the union of a visible subregion on the display (2112) and an invisible subregion (not shown) located outside the display (2112) and adjacent the visible subregion. Selectable region (4301) is associated with menu option "so", selectable region (4303) with menu option "say", selectable region (4305) with menu option "she", selectable region (4307) with menu option "suffixes", selectable region (4309) with menu option "words", selectable region (4311) with menu option "some", selectable region (4313) with menu option "show" and selectable region (4315)

with menu option "said". Also shown on the display (2112) are 12 indicating regions, each associated respectively with a menu option. Indicating region (4351) is associated with menu option "so", indicating region (4353) with menu option "say", indicating region (4355) with menu option "she", indicating region (4361) with menu option "some", indicating region (4363) with menu option "show", indicating region (4365) with menu option "said", indicating region (4371) is associated with menu option "such", indicating region (4373) with menu option "state", indicating region (4375) with menu option "school", indicating region (4381) with menu option "student", indicating region (4383) with menu option "service" and indicating region (4385) with menu option "social". Each indicating region is located on the display (2112) in the region (4350) circumscribed by the selectable regions. In accord with the Location Indication aspect of the invention, the location of each of the indicating regions (4351), (4352), (4355), (4361), (4363) and (4365) indicates the location of each of the selectable regions associated with the menu option associated with the indicating region. These selectable regions, respectively, are (4301), (4303), (4305), (4311), (4313) and (4315).

In the preferred embodiment, selection of menu option "words" causes selectable region (4301) to be associated with menu option "such" instead of menu option "so", selectable region (4303) to be associated with menu option "state" instead of menu option "say", selectable region (4305) to be associated with menu option "school" instead of menu option "she", selectable region (4311) to be associated with menu option "student" instead of menu option "some", selectable region (4313) to be associated with menu option "service" instead of menu option "show", and selectable region (4315) to be associated with menu option "social" instead of menu option "said". In the preferred embodiment, following the selection of menu option "words", the menu option newly associated with each selectable region is displayed on that selectable region (not shown). Following the selection of menu option "words", indicating regions (4371), (4373), (4375), (4381), (4383) and (4385) each indicate the location of each of the selectable regions associated with the menu option associated with the indicating region.

The indicating regions and the menu options displayed thereon in Figure 52 are disproportionately large relative to the rest of Figure 52. They are approximately 1.5 times their proportionate size. They are represented as shown in Figure 52 in compliance with Patent Cooperation Treaty Rules requiring a minimum size for letters in figures.

In the preferred embodiment of the Perimeter Menu aspect of the invention, all the menu options

displayed on the selectable regions cannot be seen in a glance by many operators. However, when the displayed menu options are displayed on the indicating regions, for example, as shown in Figure 52, the displayed menu options can be seen in a glance, facilitating searching of the menu by the operator for his intended menu option. Since the location of each selectable region is indicated by the location of the associated indicating region, the operator may point to the intended selectable region without searching it out or pausing to verify that the menu option associated with a selectable region is the menu option he desires. The frequent operator of such a menu interface may habituate the process of selecting an intended menu option so he can focus his attention on another task while selecting the option, for example, planning his next interaction with the menu interface.

Figure 53 depicts a display and structures in accord with another embodiment of the Location Indication aspect of the invention. Selectable regions (4604), (4608), (4612), (4616), (4620), (4624), (4628) and (4632) are located adjacent the display (2112) and associated respectively with menu options "so", "say", "she", "suffixes", "said", "show", "some" and "words". Each selectable region is unbounded on the side furthest from and parallel to the edge of the display. Indicating regions (4351), (4353), (4355), (4357), (4367), (4361), (4363) and (4365) are associated respectively with menu options "so", "say", "she", "suffixes", "said", "show", "some" and "words". In accord with the Location Indication aspect of the invention, the location of an indicating region indicates the location of the selectable region associated with the menu option associated with the indicating region.

The large size of the selectable regions outside the display, for example, as shown in Figure 53, facilitate selection by individuals with impaired fine motor control while the indicating regions indicate the location of each associated selectable region.

Yet another embodiment in accord with the Location Indication aspect of the invention is shown in Figures 54 and 55. Figure 54 depicts a display (2112) having thereon eight selectable regions, each associated respectively with a menu option. As shown in the Figure, selectable region (3911) is associated with menu option "aeiou", selectable region (3910) with menu option "gqjyvwxyz", selectable region (3908) with menu option "setup", selectable region (3907) with menu option undo, selectable region (3905) with menu option "control", selectable region (3904) with menu option "words", selectable region (3902) with menu option "nsrm<space>tcp" and selectable region (3901) with menu option "bdfhkl". Menu option "aeiou" is associated with a submenu which

includes submenu options "a", "e", "i", "o" and "u", displayed on indicating regions (3930), (3928), (3926), (3924) and (3922) respectively. The background pattern of indicating region (3930) matches the background pattern of selectable region (3908), indicating that submenu option "a" will be associated with selectable region (3908) following selection of menu option "aeiou".

5 Similarly, the background pattern of indicating region (3928) matches the background pattern of selectable region (3910), indicating that submenu option "e" will be associated with selectable region (3910) following selection of menu option "aeiou". Alternatively, the indication may be made by the size, shape, hue, brightness, contrast, dithering, fill, blinking, hatching or pattern of the indicating region or any part thereof, including either of the foreground and background of the  
10 indicating region.

When the operator selects selectable region (3911), the display (2112) changes to that shown in Figure 55. Now, selectable region (3910) is associated with submenu option "e", selectable region (3908) with submenu option "a", selectable region (3904) with submenu option "u", selectable  
15 region (3902) with submenu option "o" and selectable region (3901) with submenu option "i". In accord with the Location Indication aspect of the invention, the appearance of an indicating region indicates the location of the selectable regions associated with the submenu option associated with the indicating region.

20 The embodiment shown in Figures 54 and 55 illustrates how the Location Indication aspect of the invention speeds selection of a submenu option of a menu hierarchy. The operator, by observing the background pattern of the submenu option within the displayed menu option, may determine which selectable region he should next dwell on. The operator may make this determination prior to selection of the menu option and need not wait for the submenu options to be displayed on their  
25 associated selectable regions. In accordance with the Location Indication aspect of the invention, the operator may select or spell out words more quickly than with conventional automated menu hierarchy. Assuming the display (2112) is part of computer system, these words may be input to an application program, and , if the computer system is coupled to a speech synthesizer, these words may be spoken.

30

Figure 56 depicts another apparatus in accord with the Location Indication aspect of the invention. An example of the operation of this apparatus will now be described. Figure 56 depicts display area (4770) adjacent to which are located selectable regions (4701), (4703), (4705), (4707), (4709), (4711), (4713) and (4715). Not shown in the Figure are three sets of eight menu options. At

different times during the operation of the apparatus shown in Figure 56, for example at one second intervals, the plurality of selectable regions is associated with a different set of eight menu options such that, for a one second period, each selectable region is associated respectively with one menu option of the associated set of menu options. On the display area are 24 indicators, each associated  
 5 respectively with one of the menu options. Each indicator indicates when a selectable region is associated with the menu option associated with the indicator. Thus, each of the indicators (4721), (4723), (4725), (4727), (4729), (4731), (4733) and (4735) is associated respectively with a menu option which may be in turn associated respectively, for example, during a first one second period, with one of the selectable regions. The operator may select a desired one of the 24 menu options  
 10 by selecting the associated selectable region during the period when the desired menu option is associated with the associated selectable region.

Alternatively, the apparatus shown in Figure 56 may require two successive selection events, the first selection event to select a set of eight menu options or to select a set of three menu options, the  
 15 set being associated with one selectable region, and the second selection event to select one of the selected set. For example, the first selection event may select the set of menu options associated with indicators (4773), (4753) and (4733), and the second selection event may select one menu option from this set.

20 Still another apparatus in accord with the Location Indication aspect of the invention is shown in Figure 57. Figure 57 depicts display area (4770) outside of which are located selectable regions (5001), (5003), (5005), (5007), (5009), (5011), (5013), (5015), (5021), (5023), (5025), (5027), (5029), (5031), (5033) and (5035). The location of each selectable region is indicated by an indicating region on the display area, (5041), (5043), (5045), (5047), (5049), (5051), (5053),  
 25 (5055), (5061), (5063), (5065), (5067), (5069), (5071), (5073) and (5075), respectively.

The Location Indication aspect of the invention will now be described from an implementation perspective with reference to Figure 52. Preferably, the Location Indication aspect is implemented by modifications to the access program (1206) described in the detailed description of the  
 30 Perimeter Menu aspect of the invention. The modifications required for the Location Indication aspect of the invention are: (1) at initialization time: (a) create twelve child edit windows, each corresponding to one of the indicating regions shown in Figure 52, each of the class "edit", each having the style (WS\_CHILD | WS\_BORDER | WS\_DISABLED | ES\_MULTILINE |  
 AlignmentStyle) where "|" represents a logical OR operation and where AlignmentStyle equals

ES\_RIGHT for child windows having right justified text and ES\_LEFT for child windows having left justified text, as shown in Figure 52; (b) move the child edit windows so they are located in or near the center of the display; (c) display the child edit windows; and (d) initialize an array which maps each child edit window, for example, by an index between 0 and 11 inclusive, to an element of the aLabel array; and (2) modify the code implementing ST\_SELECTED state processing, so that after changing the menu options associated with various selectable regions (by changing the pLabel element of the data set associated with each of the state machines to point to the menu option in the aLabel array to be associated with that state machine), the array mapping each child window to an element of the aLabel array is used to access the text of the menu option and the text of each child edit window is set accordingly. In the preferred embodiment, the six menu options displayed in indicating regions (4371), (4374), (4375), (4381), (4383) and (4385) are present in the aLabel array when Figure 52 is shown, but are not associated with selectable regions until the operator selects menu option "words".

#### 15 I. Sound Match

The preferred embodiment of the Sound Match aspect of the invention will now be described in detail from a functional perspective using an example depicted in Figure 58. Figure 58 shows a display (2112) of a computer system (2116) having thereon six regions or sound indicators, (5801), (5803), (5805), (5807), (5809), and (5811), each associated with a menu option, "ypgqj", "ldhbfk", "wizen", "words", "vort x", and "sumac", respectively. Each menu option is displayed on its associated sound indicator. Each sound indicator has a distinct hue. For example, sound indicator (5801) may be green, (5803) white, (5805) blue, (5807) red, (5809) orange and (5811) grey. Each of these sound indicators indicates a sound the operator is able to consistently produce. for example, the vowel sound e as it sounds in green, i as it sounds in white, u as it sounds in blue, e as it sounds in red, o as it sounds in orange and e it sounds in grey. Assuming the operator says o as it sounds in orange, "vort x", the menu option associated with the orange sound indicator (5809) is selected and the display is changed to that shown in Figure 59. In the preferred embodiment, submenu options space, "x", "r", "t", "v" and "o" are now associated with each of the sound indicators (5901), (5903), (5905), (5907), (5909), and (5911) respectively. Assuming the operator says e as in green, submenu option space is selected and a space is input to the application program (6107) whose output appears in region (5850).

Figure 60 illustrates a display and structures in accordance with an alternative embodiment of the

Sound Match aspect of the invention. Figure 60 depicts a display (2112) of a computer system (2116). Adjacent the display (2112) is a static display (6252) having thereon eight sound indicators (6204), (6208), (6212), (6216), (6220), (6224), (6228), and (6232). Each of the eight sound indicators is a symbol in a phonetic character set graphically representing a sound. Alternatively, the sound indicators may include a picture of an object, for example, a tree, a house, a boy, or a map of a country, or may include a shape, for example, a square, a circle, or a triangle, or may include a hue indicator, a pitch indicator, a volume indicator, a sound duration indicator, a change in pitch indicator, or a change in volume indicator. Eight menu options, "vort<space>x", "sumac", "wizen", undo, "words", "talk", "ldhbfk" and "ypgqj", are displayed on the display (2112), each adjacent and associated respectively with one of the sound indicators, the eight menu options together circumscribing region (6250) on the display. The operator may select any one of the menu options by producing the sound indicated by the sound indicator associated with the menu option. In response to a menu selection, submenu options of the selected menu option may be displayed and associated respectively with a sound indicator.

An operator with impaired speech but who is able to consistently produce a relatively small number of sounds distinguishable by conventional speech recognition means may, in accord with the Sound Match aspect of the invention, select from among the small number of menu options by using the sounds he can produce. Assuming the display (2112) is part of computer system, the menu option may represent inputs to an application program, and, if the computer system is coupled to a speech synthesizer, the menu option may represent words to be spoken.

Figure 61 illustrates a display and structures in accordance with an alternative embodiment of the Sound Match aspect of the invention. Figure 61 depicts a display (2112) of a computer system (2116) having thereon six square sound indicators, (6401), (6403), (6405), (6411), (6413), and (6415) arranged in two columns of three sound indicators. Each sound indicator abuts a sound indicator in the other column, the sound indicator located above it, if any, and the sound indicator located below it, if any. Assume that the operator is entering Chinese, that he uses a keyboard to enter a phonetic unit and intonation according to the Pin Yin coding method for the Chinese language, and that he enters the distinct sound "fú", each of the sound indicators shown in Figure 61 is associated respectively with a menu option, each of the plurality of menu options having a common characteristic. In this example, the menu options are homophones and the common characteristic is a phonetic unit and intonation but may be a phonetic unit alone, an intonation alone, a stroke used to draw an ideograph, a number of horizontal strokes, a number of vertical

strokes, a number of total strokes, a stroke order, a radical, a part of speech, an ideograph, a kana, a diacritic, a classification of a part of an ideograph or other characteristic of a class of ideographs. Each of the sound indicators has a distinct hue. The operator may select any one of the displayed menu options, according to the Sound Match aspect of the invention, by speaking the sound  
5 associated with the sound indicator associated with the desired menu option. For example, assume the operator says, "blue" or a translation thereof, preferably a Chinese translation in this example. The ideograph located on the blue sound indicator is selected. In this example, this ideograph is input to a word processing program and appears on the display (2112).

10 The Sound Match aspect of the invention thus allows an operator to select from an option from a menu, using speech recognition means, whether or not the menu options are homophones. The operator does not need to use his hands to make this selection and so may keep both his hands on the home row of the keyboard, in preparation for entering the next common characteristic, or, if specifying the common characteristic by voice, may select a menu option without interrupting the  
15 manual activity he's engaged in.

The preferred embodiment of the Sound Match aspect of the invention will now be described in detail from an implementation perspective, beginning with the hardware and software operating environment which will now be described with reference to Figure 62 which depicts a speech  
20 recognition system (6001) including a computer system (2116) and keyboard (2210), as earlier described, a sound board (6007) and a microphone (6009). The conventional computer system (2116) preferably includes an 80486 CPU running at 33MHz or faster, and is provided with Dragon Dictate Power Edition software, available from Dragon Systems, Inc., Newton, Massachusetts, USA. Preferably, the sound board is the Audio Capture Playback Adaptor and the microphone is  
25 the Shur Headset microphone, both available from Dragon Systems, Inc. Figure 63 depicts the software environment of the preferred embodiment, which includes the earlier described Windows® version 3.1 operating system (1204), an optional Windows® application program (6107), the Windows® Dragon software driver (6101) included in the Dragon Dictate Power Edition software, the Dragon Application (6103) included in the Dragon Dictate Power Edition  
30 software, and a speech recognition access program (6105). The Dragon Application (6103) is configured to match a sample of each of six sounds distinguishable by the Dragon Application (6103) which the operator can consistently produce. Using the example described above, these are the vowel sounds produced by the operator of e as it sounds in green, i as it sounds in white, u as it sounds in blue, e as it sounds in red, o as it sounds in orange and e it sounds in grey. Each of these

sounds is associated respectively with an identifier, for example, a number or a sequence of one or more characters. The speech recognition access program (6105) is preferably a Windows® application program developed using, in part, the Voice Tools Software Development Kit available from Dragon Systems, Inc. At initialization time, the speech recognition access program (6105) defines an array of data structures defining the menu and submenu options and the menu hierarchy. For example, one of the elements of this array determines that, on selection, certain actions are to be taken, for example, inputting text to an application program, and that certain submenu options and related data are to be associated with certain child edit windows. Also at initialization time, the speech recognition access program (6105) initializes callback procedures using the Dragon Application's Application Program Interface to receive notification from the Dragon Application when a sound has been matched. Also at initialization time, the main window of the speech recognition access program (6105) is preferably sized to just encompass the sound indicators shown in Figure 58. Also at initialization time, the speech recognition access program (6105) creates six child edit controls, each corresponding to one of the sound indicators shown in Figure 58. Each of the child edit controls has the background color described above and a text color of black or white depending upon which provides better contrast against the background color of the child edit control, and each is located on the display (2112) as shown in Figure 58. Also at initialization time, the menu options of the initial menu are each associated respectively with one of the child edit controls. After initialization, the speech recognition access program (6105), upon notification from the Dragon Application that a sound has been received and a match attempted, sequentially searches the list of identifiers matched to the sound by the Dragon Application (6103), starting with the best match, until it finds an identifier corresponding to any one of the six sounds distinguishable by the Dragon Application (6103). Assuming the operator says o as it sounds in orange, the Dragon Application (6103) provides to the speech recognition access program (6105) a list of matches including, before any other identifier corresponding to any one of the six sounds distinguishable by the Dragon Application (6103), the identifier associated with child edit control (5809). This child edit control is currently associated with menu option "vort x", the matched menu option. The speech recognition access program (6105) then sets the text of each of the child edit controls to one of the submenu options associated with the matched menu option. In the example above, submenu options space, "x", "r", "t", "v" and "o" are associated with each of the child edit controls respectively and the text of the associated child edit control is set to the submenu option. Assuming the operator says e as in green, submenu option space is the matched submenu option and a space is input to the application program (6107) whose output appears in region (5850). Preferably the application program (6107) is an application program capable of executing

a WM\_SIZE command so that the speech recognition access program (6105) may size the windows of the application program (6107) to fit neatly in region (5850) and is capable of executing WM\_CHAR messages so that the speech recognition access program (6105) may input characters to the application program (6107).

5

#### J. Ideographic Language

The preferred embodiment of the Ideographic Language aspect of the invention will now be described in detail from a functional perspective using an example depicted in Figure 64. Figure 10 64 shows the display (2112) of a general purpose computer system (2218 in Figure 15) and 12 selectable regions. Each of the 12 selectable regions consists of the union of a visible subregion on the display (2112) and an invisible subregion located outside the display (2112) and adjacent the visible subregion. For example, the selectable region in the upper left corner both above and below the top of the display (2112) in Figure 64 consists of invisible subregion (3604) and visible 15 subregion (3606), and hereinafter is referred to as selectable region (3604/3606). The other selectable regions shown in Figure 64, proceeding counter clockwise from selectable region (3604/3606) are (3608/3610), (3612/3614), (3616/3618), (3620/3622), (3624/3626), (3644/3646), (3648/3650), (3652/3654), (3656/3658), (3660/3662) and (3664/3666). In Figure 64 each of the visible subregions is adjacent an edge of the display (2112). The selectable regions together 20 circumscribe region (3680) in the center of the display. Also shown on the display (2112) within region (3680) in Figure 64 are ten square indicating regions arranged in two columns of five indicating regions. Each indicating region abuts an indicating region in the other column, the indicating region located above it, if any, and the indicating region located below it, if any. In the preferred embodiment, each indicating region indicates by its location the location of a respectively 25 associated selectable region, in accord with the Location Indication aspect of the invention. For example, the uppermost indicating region in the left column of indicating regions (3605) is associated with the uppermost selectable region (3604/3606) on the left side of the display. Indicating region (3609) located immediately below indicating region (3605) is associated with selectable region (3608/3610) located immediately below selectable region (3604/3606).

30

The operation of the example of the preferred embodiment of the Ideographic Language aspect of the invention will now be described. Assuming that the operator is fitted with a head pointer coupled to the general purpose computer system (2218), that he uses a keyboard to enter a phonetic unit and intonation according to the Pin Yin coding method for the Chinese language, and that he

enters the distinct sound "fú", each of the plurality of the selectable regions shown in Figure 64 is associated with one of a plurality of menu options, each of the plurality of menu options having a common characteristic. In this example, the common characteristic is a phonetic unit and intonation but may be a phonetic unit alone, an intonation alone, a stroke used to draw an ideograph, a number of horizontal strokes, a number of vertical strokes, a number of total strokes, a stroke order, a radical, a part of speech, an ideograph, a kana, a diacritic, a classification of a part of an ideograph or other characteristic of a class of ideographs. The ten menu options shown in Figure 64 are Chinese ideographs each starting with the distinct sound "fú". Alternatively, the menu options may be sequences of graphic symbols including one or more kanji. In Figure 64 the Chinese ideographs are each displayed on the visible subregion of the associated selectable region and on the indicating region associated with the selectable region. The remaining two of the 12 selectable regions, (3624/3626) and (3644/3646), are associated with menu options for undo and for displaying more menu options, respectively. In the preferred embodiment, in response to the selection of the menu option for displaying more menu options, each of the selectable regions associated with a menu option starting with the distinct sound "fú" is associated with a menu option not previously displayed and the newly associated menu option replaces the old menu option on the display.

Resuming now with the description of the example of the preferred embodiment, a cross hair cursor (3686) is displayed in the circumscribed region (3680). Assuming the operator desires to select the menu option associated with selectable region (3608/3610), he turns his head to the left and the cross hair cursor (3686) moves to the left, responsive to the head movement, until the cross hair cursor hotspot intersects selectable region (3608/3610) and he maintains the location of the cross hair cursor hotspot on that selectable region for the selection threshold period. The menu option associated with selectable region (3608/3610) is selected and added to text (3684) displayed in the circumscribed region (3680), the general purpose computer system (2218) emits an audible beep indicating that selection has occurred and the displayed menu options, both on the indicating regions and the visible subregions, are removed from the display.

In the preferred embodiment, selection is made in accord with the Facilitated Dwell subaspect of the Dwell aspect of the invention, described above. Thus, the operator receives an indication of the progress of his selection by a change in appearance of the indicating region associated with the intersected selectable region.. Alternatively, selection may be by intersection of a location indicated by the at least part of a cursor and a selectable region alone, by such an intersection

accompanied by a switch operation, for example, a depression of a space bar on the keyboard, or by other suitable means.

In accord with the Location Indication aspect of the invention, the operator sees the entire menu in the compact indicating regions and may discover the location of the selectable region associated with each menu option without having to visually scan all the visible subregions. In the preferred embodiment, the plurality of indicating regions may be moved to a different location on the display to avoid obstructing the area of the display showing most recently added graphic symbols or the area of the display where graphic symbols will soon be added. In accord with the Ideographic Language aspect of the invention, an operator may select from among many sequences of one or more ideographs without lifting either hand from the keyboard, thus speeding entry of single ideographs or sequences of ideographs in word processing systems for the Chinese, Japanese and Korean languages. Since, in the preferred embodiment, the selectable regions are located adjacent the edge of the display, a large rectangular region remains available on the display for the output of an application program. Further, if the selectable regions are located entirely outside the display, the indicating regions obstruct only a relatively small portion of the circumscribed region (3680), permitting the display of a sequences of ideographs for selection simultaneous with the display of previously selected ideographs, neither obstructing the operator's view of the other. If the general purpose computer system is coupled to a speech synthesizer and the ideographs are symbols of a symbol set, for example, the Blissymbolics Symbol Set, an illiterate operator, for example, a school child having impaired speech, may select symbols associated with words and those words may be spoken via the speech synthesizer.

Figure 65 illustrates a display and structures in accordance with an alternative embodiment of the Ideographic Language aspect of the invention. In this Figure, 18 selectable regions (3704/3706), (3708/3710), (3712/3714), (3716/3718), (3720/3722), (3724/3726), (3728/3730), (3732/3734), (3736/3738), (3740/3742), (3744/3746), (3748/3750), (3752/3754), (3756/3758), (3760/3762), (3764/3766), (3768/3770), (3772/3774) and (3776/3778) circumscribe region (3780) on the display (2112). The visible subregions of four of the 18 selectable regions abut each of the top, left and right edges of the display (2112). The visible subregions of six of the 18 selectable regions abut the bottom edge of the display (2112). The 18 indicating regions are located within the top half of region (3780). 12 of the 18 indicating regions are arranged in two columns of six indicating regions each. The column on the left is close to the visible subregions abutting the left edge of the display. The column on the right is close to the visible subregions abutting the right edge of the

display. Two of the 18 indicating regions are located between the top indicating regions in each of the left and right columns. The remaining four of the 18 indicating regions are located between the bottom indicating regions in each of the left and right columns. Each of the four indicating regions in the top row of indicating regions indicates the location of a respectively associated selectable region along the top edge of the display. Each of the six indicating regions in the bottom row of indicating regions indicates the location of a respectively associated selectable region along the bottom edge of the display. Each of the middle four indicating regions in each of the left and right columns of indicating regions indicates the location of a respectively associated selectable region along the left and right edge of the display. The 16 menu options shown in Figure 65 are Chinese ideographs each of which includes the radical kōu, a radical having the shape of a rectangle. Each ideograph is displayed on the visible subregion of the associated selectable region and on the indicating region associated with the selectable region. The remaining two of the 18 selectable regions, (3724/3726) and (3744/3746), are associated with menu options for undo and for displaying more menu options, respectively.

The indicating regions (3782) in Figure 65 are disproportionately large relative to the rest of Figure 65. They are approximately 1.5 times their proportionate size. They are represented as shown in Figure 65 in compliance with Patent Cooperation Treaty Rules requiring a minimum size for letters in figures.

Figure 66 illustrates a display and structures in accordance with an alternative embodiment of the Ideographic Language aspect of the invention. Figure 66 depicts a display (2112) of a computer system (2116) having thereon ten square indicating regions, (3801), (3803), (3805), (3807), (3809), (3811), (3813), (3815), (3817), and (3819), arranged in two columns of five indicating regions.

Each indicating region abuts an indicating region in the other column, the indicating region located above it, if any, and the indicating region located below it, if any. Each indicating region indicates the location of a respectively associated selectable region (not shown) outside the display. Assume that the operator is entering Chinese and uses a keyboard coupled to the computer system (2116) to enter the distinct sound "fú". On each of the indicating regions is then displayed an ideograph having with the distinct sound "fú". The operator, using a pointer coupled to the computer system (2116), points to the selectable region associated with the indicating region on which is displayed the desired ideograph. The selectable region is selected in response to a selection event, and, in this example, the associated menu option is input to a word processing program and appears on the display (2112).

Figure 67 illustrates a display and structures in accordance with an alternative embodiment of the Ideographic Language aspect of the invention. Figure 67 depicts a display (2112) of a computer system (2116) having thereon eight selectable regions (6701), (6703), (6705), (6707), (6709), (6711), (6713), and (6715), each located on the display (2112) adjacent the edge of the display (2112) and associated respectively with a menu option. Together the eight selectable region circumscribe region (6750) on the display. In Figure 67 each of eight menu options is displayed on its associated selectable region. Six of the eight menu options, associated with selectable regions (6703), (6705), (6707), (6701), (6715), and (6713) each represent a sequence of graphic symbols in the Japanese language. These sequences, in Romanized Japanese are respectively "hoka", "hoka ni", "hoka no", "hoka kara", "nanika hoka nomono", and "hoka demo nai ga". Each sequence includes the kanji "hoka" shown alone on selectable region (6703). The sequences are ordered by length, the shorter sequences on selectable regions on the left side of the display (2112) ordered by length from the top to the bottom of the display (2112), the longer sequences along the right side of the display (2112) ordered by length from the top to the bottom of the display (2112). The remaining two of the eight selectable regions, (6709) and (6711), are associated with menu options for displaying the previous and the next display of menu options, respectively. The menu option associated with a selectable region may be selected by a selection event.

The preferred embodiment of the Ideographic Language aspect of the invention will now be described in detail from an implementation perspective. Preferably, the Ideographic Language aspect of the invention is implemented by modifications to the access program (1206) described in the detailed description of the Perimeter Menu aspect of the invention, modified as described in the descriptions of the Facilitated Dwell subaspect and the Location Indication aspects of the invention. The modifications required for the Ideographic Language aspect of the invention are: (1) install on the general purpose computer system a font for the ideographic language of the embodiment; (2) at initialization time: (a) set the text of all labels for display on the selectable regions to null; (b) do not enable the cursor polling timer; and (c) hide the Windows® (1204) system cursor; (3) include in the main window processing procedure of the access program (1206) code to process WM\_CHAR messages and, when a sequence of one or more WM\_CHAR messages indicates a common characteristic: (a) lookup sequences or representations of sequences of one or more ideographs (hereinafter "sequences") having the common characteristic; (b) copy ten of the sequences to the labels; (c) set the Windows® (1204) system cursor to the cross hair cursor, set the cursor location to a predetermined location near an indicating region and show the Windows® (1204) system cursor; (d) set fPaint to TRUE for every state machine; (e) send

EV\_RESET to every state machine; (f) display each sequence at the appropriate location in the indicating region; and (g) enable the cursor polling timer; and (4) add state processing to ST\_SELECTED to: (a) set the text of all labels for display to null; (b) hide the Windows® (1204) system cursor; (c) erase all sequences from the indicating region; (d) disable the cursor polling timer; (e) set fPaint to TRUE for every state machine; (f) send EV\_RESET to every state machine; and (g) insert the selected sequence into the work space.

In the above descriptions, there is shown and described only the preferred and certain alternate embodiments of each aspect of the invention, but, as aforementioned, it is to be understood that each aspect of the invention is capable of use in various other combinations and environments and is capable of changes or modifications within the scope of the inventive concepts as expressed herein.

            set event to EV_MOVEMENT for all selectable
            regions
    else
        if cursor hotspot intersects a selectable region
25        if idle time exceeded
            set event to EV_IDLE_TIMEOUT for all selectable
            regions
        else
            if intersected selectable region's Color equals
30            Ceiling
                set event to EV_CEILING for the intersected
                selectable region and to EV_DECAY for all
                other selectable regions
            else
```

```
        set event to EV_DWELL for the intersected
        selectable region and to EV_DECAY for all
        other selectable regions

    else
5        set event to EV_DECAY for all selectable regions

        set the previous cursor hotspot location to the current
        hotspot location
    }
10 /* end CreateEvent */
```

## Claims

I claim:

1. For use with a human interface system wherein a body member of an operator may indicate a  
5 first location on a surface, the surface including a display area, a method of selecting a sequence of one or more graphic symbols from a plurality of sequences of one or more graphic symbols, one or more sequences of the plurality of sequences including one or more ideographs, said method comprising the steps of:  
10 displaying on the display area a plurality of selectable regions, the plurality of selectable regions together at least partially circumscribing a region on the display area, at least two of the selectable regions associated respectively with one sequence of the plurality of sequences, each of the plurality of sequences having a first common characteristic; and  
15 in response to a selection event wherein the first location indicated by the body member at or near the time the selection event occurs intersects any one of the at least two selectable regions, selecting the sequence associated with the intersected selectable region.
2. The method of claim 1 wherein each of the sequences belongs to any one of the Chinese  
20 language, Japanese language, Korean language, Picture Communication Symbols symbol set, Rebus symbol set, Picsyms symbol set, Pictogram Ideogram Communication Symbols symbol set, Yerkish symbol set, Blissymbolics symbol set, and a set of depictions of the signs of a manual sign language.
- 25 3. The method of claim 1 further comprising confining the first location indicated by the body member of the operator to the display area.
4. The method of claim 1 wherein the operator keeps at least five of his fingers, not including  
30 either thumb, on the home row of a keyboard while moving the body member to indicate the first location on the surface.
5. The method of claim 1 wherein the first common characteristic includes any one of:  
(a) a phonetic unit, including either one of a Chinese pronunciation and a Japanese pronunciation;

- (b) an intonation;
  - (c) a stroke used to draw an ideograph;
  - (d) a number of horizontal strokes;
  - (e) a number of vertical strokes;
  - 5 (f) a number of total strokes;
  - (g) a stroke order;
  - (h) a radical;
  - (i) a part of speech;
  - (j) an ideograph;
  - 10 (k) a kana;
  - (l) a diacritic;
  - (m) a classification of a part of an ideograph;
  - (n) a meaning; and
  - (o) a meaning class.
- 15
6. The method of claim 1 wherein the body member of the operator is a body member other than the shoulder, arm, elbow, wrist, hand, finger, or thumb.
7. The method of claim 6 wherein the body member of the operator is the head of the operator.
- 20
8. The method of claim 1 wherein the displaying step further comprises displaying a first cursor on the display area at the first location indicated by the body member; and wherein the selecting step further comprises removing the first cursor from the display area.
- 25
9. The method of claim 8 wherein the selecting step further comprises displaying a second cursor at a predetermined location on the display area.
- 10
10. The method of claim 1 further comprising displaying on the display area one sequence of the plurality of sequences associated with one of the at least two selectable regions.
- 30
11. The method of claim 10 wherein the selecting step further comprises displaying a first cursor on the display area at a location on or near the displayed sequence.
12. The method of claim 10 wherein the step of displaying one sequence of the plurality of

sequences further comprises indicating the association of the displayed sequence with its associated selectable region.

13. The method of claim 12 wherein the indicating step further comprises displaying any part of  
5 either of:

- (a) the foreground of the displayed sequence; and
- (b) the background of the displayed sequence

in any one of:

- (1) a location;
- 10 (2) a size;
- (3) a shape;
- (4) a hue;
- (5) a brightness;
- (6) a contrast;
- 15 (7) a tone;
- (8) a dithering;
- (9) a fill; and
- (10) a font

associated with the associated selectable region.

20

14. The method of claim 1 further comprising selecting the first common characteristic from a plurality of common characteristics of ideographs.

15. The method of claim 1 wherein the selection event includes a switch operation.

25

16. The method of claim 1 wherein at least one sequence of the plurality of sequences includes one or more graphic symbols in addition to the graphic symbols of the at least one sequence representing the first common characteristic.

30

17. The method of claim 16 wherein the first common characteristic includes an ideograph and the additional graphic symbols of the at least one sequence include any one of:

- (a) a prefix;
- (b) an infix; and
- (c) a suffix;

which may be added to the ideograph.

18. The method of claim 1 wherein the at least two of the selectable regions are ordered responsive to any one of:
- 5 (a) the frequency of use of the associated sequence in an ideographic language;
  - (b) the frequency of use of the associated sequence in a predetermined operator's usage;
  - (c) the recency of use of the associated sequence in a predetermined operator's usage;
  - (d) the length of associated sequence;
  - (e) the alphabetic order of the associated sequence; and
  - 10 (f) a second common characteristic.
19. For use with a human interface system including a keyboard wherein a body member of an operator may indicate a first location on a surface, the surface including a display area, a method of selecting a sequence of one or more graphic symbols from a plurality of sequences
- 15 of one or more graphic symbols, one or more sequences of the plurality of sequences including one or more ideographs, said method comprising the steps of:
- displaying on the display area a plurality of selectable regions, at least two of the selectable regions associated respectively with one sequence of the plurality of sequences, each of the
- 20 plurality of sequences having a common characteristic;
- moving the body member to indicate the first location on the surface while at least five of the operator's fingers, not including either thumb, remain on the home row of the keyboard; and
- 25 in response to a selection event wherein the first location indicated by the body member at or near the time the selection event occurs intersects any one of the at least two selectable regions, selecting the sequence associated with the intersected selectable region.
20. The method of claim 1 or 19 wherein the body member may indicate a second location on the
- 30 surface and wherein the selection event includes the duration of a period of intersection equalling or exceeding a selection threshold period, the period of intersection starting in response to the first location intersecting any one of the selectable regions and ending in response to the second location intersecting the selectable region intersected by the first location.

21. For use with a human interface system wherein a body member of an operator may indicate a location outside a display area, a method of selecting a sequence of one or more graphic symbols from a plurality of sequences of one or more graphic symbols, one or more  
5 sequences of the plurality of sequences including one or more ideographs, said method comprising the steps of:

at least partially delimiting a plurality of selectable regions outside the display area, at least two of the selectable regions associated respectively with one sequence of the plurality of  
10 sequences, each of the plurality of sequences having a common characteristic; and

in response to a selection event wherein the location indicated by the body member at or near the time the selection event occurs intersects any one of the at least two selectable regions, selecting the sequence associated with the intersected selectable region.

15

22. The method of claim 21 wherein the body member of the operator is a body member other than either of the operator's eyes.

23. For use with a human interface system wherein a body member of an operator may indicate  
20 successive locations on a surface, the surface including a display area, a method of selecting a sequence of one or more graphic symbols from a plurality of sequences of one or more graphic symbols, one or more sequences of the plurality of sequences including one or more ideographs, said method comprising the steps of:

25 at least partially delimiting a plurality of selectable regions, each of the selectable regions including an invisible subregion adjacent the display area and a visible subregion on the display area, the plurality of visible subregions together at least partially circumscribing a region on the display area, at least two of the selectable regions associated respectively with one sequence of the plurality of sequences, each of the plurality of sequences having a  
30 common characteristic; and

responsive to the duration of a period of intersection equalling or exceeding a selection threshold period, the period of intersection starting in response to a starting location intersecting any one of the invisible subregions included in one of the at least two selectable

regions and ending in response to an ending location intersecting the invisible subregion intersected by the starting location, the starting and the ending locations each being one of the successive locations, selecting the sequence associated with the selectable region including the invisible subregion intersected by the starting location.

5

24. The method of claim 23 further comprising indicating the duration of a period of intersection, said period starting in response to the starting location and ending in response to an intermediate location intersecting the invisible subregion intersected by the starting location, the intermediate location being one of the successive locations occurring after the starting location.

10

25. For use with a human interface system wherein a body member of an operator may indicate successive locations on a surface, the surface including a display area, a method of selecting a sequence of one or more graphic symbols from a plurality of sequences of one or more graphic symbols, one or more sequences of the plurality of sequences including one or more ideographs, said method comprising the steps of:

15

displaying on the display area a plurality of selectable regions, the plurality of selectable regions together at least partially circumscribing a region on the display area, at least two of the selectable regions associated respectively with one sequence of the plurality of sequences, each of the plurality of sequences having a common characteristic; and

20

responsive to a quantity equalling or exceeding a selection threshold period, said quantity being a function of the durations of a first and a second period of intersection

25

said first period of intersection starting in response to a first starting location intersecting any one of the at least two selectable regions and ending in response to a first ending location intersecting the selectable region intersected by the first starting location,

30

said second period of intersection starting in response to a second starting location intersecting the selectable region intersected by the first starting location and ending in response to a second ending location intersecting the selectable region intersected by the first starting location.

the first starting location, the second starting location, the first ending location and the second ending location each comprising one of the successive locations.

selecting the sequence associated with the selectable region intersected by the first starting location.

5

26. The method of claim 25 further comprising increasing the selection threshold period responsive to the duration of an intermediate period of non-intersection of the selectable region intersected by the first starting location, said intermediate period of intersection starting in response to an intermediate starting location not intersecting the selectable region intersected by the first starting location and ending in response to an intermediate ending location not intersecting the selectable region intersected by the first starting location, the intermediate starting and the intermediate ending locations each comprising one of the successive locations and each occurring at the time or after the first ending location occurs and before or at the time the second starting location occurs.

10

15

27. The method of claim 26 further comprising indicating the duration of the intermediate period of non-intersection.

20

28. A method of selecting a sequence of one or more graphic symbols from a plurality of sequences of one or more graphic symbols, one or more sequences of the plurality of sequences including one or more ideographs, said method comprising the steps of:

25

displaying on a display a plurality of selectable regions, each of the selectable regions associated respectively with one sequence of the plurality of sequences, each of the plurality of sequences having a common characteristic;

30

receiving a movement related signal and moving a cursor on the display responsive thereto; and

selecting the sequence associated with the particular one of the plurality of selectable regions most nearly along a path indicated by a cursor location and the movement related signal in advance of an intersection of the cursor and said particular selectable region.

29. A method of selecting a sequence of one or more graphic symbols from a plurality of sequences of one or more graphic symbols, one or more sequences of the plurality of sequences including one or more ideographs, said method comprising the steps of:

5 displaying on a display a plurality of selectable regions, each of the selectable regions associated respectively with one sequence of the plurality of sequences, each of the plurality of sequences having a common characteristic;

10 receiving a movement related signal and moving a cursor on the display responsive thereto; and

responsive to:

- 15 (a) an intersection of the cursor and a selectable region; and  
(b) a cursor path toward the intersected selectable region,

selecting the sequence associated with the intersected selectable region.

30. The method of claim 29 wherein the selecting step is further responsive to the duration of the period of the intersection equalling or exceeding a selection threshold period.

31. For use with a human interface system wherein a body member of an operator may indicate successive locations on a surface, the surface including a display area, a method of selecting an undo function, said method comprising the steps of:

25 first displaying on the display area a plurality of selectable regions, the plurality of selectable regions together at least partially circumscribing a region on the display area, at least two of the selectable regions associated respectively with one sequence of a plurality of sequences of graphic symbols, one or more sequences of the plurality of sequences including one or more ideographs and each having a common characteristic;

30 in response to a first selection event wherein a first one of the successive locations indicated by the body member at or near the time the first selection event occurs intersects any one of the at least two selectable regions, selecting the sequence associated with the intersected

selectable region;

performing a function with the selected sequence:

5       second displaying on the display area a selectable region associated with the undo function:  
and

in response to a second selection event wherein a second one of the successive locations  
indicated by the body member at or near the time the second selection event occurs intersects  
10       the selectable region associated with the undo function, undoing the function performed with  
the selected sequence.

32. A method of data entry in an ideographic language, said method comprising the steps of:

15       displaying on a display a plurality of selectable regions, the plurality of selectable regions  
together at least partially circumscribing a region on the display, at least two of the selectable  
regions associated respectively with one sequence of a plurality of sequences of graphic  
symbols, one or more sequences of the plurality of sequences including one or more  
ideographs and each having a common characteristic;

20       receiving a movement related signal and moving a cursor on the display responsive thereto:

responsive to a cursor path toward any one of the at least two selectable regions, changing a  
selection threshold period associated or to be associated with said selectable region: and

25       responsive to the duration of a period of intersection of the cursor and said selectable region  
equalling or exceeding the selection threshold period, entering into the at least partially  
circumscribed region the sequence associated with said selectable region.

30       33. For use with a speech synthesis system including a speech synthesizer and a display, a  
method of speaking comprising the steps of:

displaying on the display a plurality of selectable regions, the plurality of selectable regions  
together at least partially circumscribing a region on the display, at least two of the selectable

regions associated respectively with one sequence of a plurality of sequences of graphic symbols, one or more sequences of the plurality of sequences including one or more ideographs and each having a common characteristic;

5 moving a cursor on the display responsive to the movement of a body member of an operator; and

in response to a selection event wherein the cursor at or near the time the selection event occurs intersects any one of the at least two selectable regions, speaking, by means of the  
10 speech synthesizer, a word associated with the sequence associated with the intersected selectable region.

34. An apparatus for selecting a menu option from a plurality of menu options, said apparatus comprising:

- 15 (a) display means for displaying on a display the plurality of menu options, each of the plurality of menu options associated respectively with a sound;
- (b) sound receiving means for receiving a sound signal;
- (c) match means for matching the received sound signal to any one of the plurality of sounds; and
- 20 (d) selection means for selecting the menu option associated with the matched sound.

35. The apparatus of claim 34 wherein one or more of the menu options represents a sequence of one or more letters and the sound associated with each of the one or more menu options is not a phonetic representation of the menu option.

25 36. The apparatus of claim 34 wherein each of the plurality of sounds is associated respectively with a sound indicator other than the displayed menu option.

37. The apparatus of claim 36 further comprising indication means for indicating the association  
30 of each sound indicator to the menu option associated with the sound associated with the sound indicator.

38. The apparatus of claim 37 wherein each of the sound indicators is outside the display.

39. The apparatus of claim 36 wherein one or more of the sound indicators includes a non-alphanumeric indicator.
40. The apparatus of claim 39 wherein the non-alphanumeric indicator includes any one of a hue indicator, a pitch indicator, a volume indicator, a sound duration indicator, a change in pitch indicator, a change in volume indicator, a shape indicator, and an object indicator.
41. For use with a general purpose computer system including a display, an apparatus for selecting a menu option from a plurality of menu options, said apparatus comprising:
- (a) display means for displaying on the display the plurality of menu options, each of the plurality of menu options associated respectively with a hue displayed intersecting or near the displayed menu option;
  - (b) sound receiving means for receiving a signal representing a sound;
  - (c) match means for matching the received sound to a name of any one of the plurality of hues; and
  - (d) selection means for selecting the menu option associated with the hue corresponding to the matched name.
42. The apparatus of claim 34 or 41 wherein the plurality of displayed menu options together at least partially circumscribe a region on the display.
43. An apparatus for selecting a menu option from a plurality of menu options, said apparatus comprising:
- (a) a surface on which may be displayed the plurality of menu options, each of the plurality of menu options associated respectively with a sound indicator other than the displayed menu option;
  - (b) a sound matcher for matching a sound to any one of the plurality of sound indicators; and
  - (c) a selector for selecting the menu option associated with the matched sound indicator.
44. For use with a computer capable of executing an application program, a computer access device, said device comprising:
- (a) a menu hierarchy including a menu including a plurality of menu options, one or more of the menu options associated respectively with a sound which is not a phonetic

representation of the menu option and with a submenu including a plurality of submenu options, each of the submenu options associated respectively with a sound which is not a phonetic representation of the submenu option and with a sequence of one or more characters;

- 5 (b) sound receiving means for receiving a first and a second sound signal;
- (c) match means for matching the first sound signal to any one of the sounds associated with the one or more menu options and for matching the second sound signal to any one of the sounds associated with the submenu options; and
- 10 (d) input means, responsive to the match means matching the first and the second sound signals, for inputting to the application program the sequence of one or more characters associated with the submenu option associated with the sound matched by the second sound signal.

45. The computer access device of claim 44 further comprising:

- 15 (e) a display; and
- (f) means for displaying the one or more menu options on the display, and, responsive to the match means matching the first sound signal, displaying the submenu options on the display.

20 46. For use with a general purpose computer system including a display on which may be displayed a plurality of menu options; and including sound receiving means for receiving a sound signal, an apparatus for selecting a menu option from the plurality of menu options, said apparatus comprising:

- (a) a medium readable by the general purpose computer system; and
- 25 (b) a program, stored on the medium and executable by the general purpose computer system, for:
- (1) displaying on the display the plurality of menu options, each of the plurality of menu options associated respectively with a sound which is not a phonetic representation of the menu option;
- 30 (2) matching the received sound signal to any one of the plurality of sounds; and
- (3) selecting the menu option associated with the matched sound.

47. The apparatus of claim 46 wherein the medium includes a random access memory.

48. The apparatus of claim 46 wherein the medium is coupled to the general purpose computer system.
49. The apparatus of claim 46 wherein the medium may be coupled to and uncoupled from the general purpose computer system.
50. The apparatus of claim 46 wherein the medium includes either one of a magnetic store and an optical store.
51. A speech synthesis system comprising:
- (a) a display for displaying a plurality of menu options, each of the menu options associated respectively with a sound and with a sequence of one or more characters;
  - (b) sound receiving means for receiving successive sound signals;
  - (c) a speech synthesizer; and
  - (d) control means for
    - (1) matching one of the successive sound signals to any one of the plurality of sounds;
    - (2) repetitively
      - (I) selecting the sequence of one or more characters associated with the menu option associated with the matched sound; and
      - (ii) appending the selected sequence to at least one previously selected sequence; and
    - (3) speaking, by means of the speech synthesizer, the word spelled by the appended sequences.
52. A method of selecting a sequence of one or more graphic symbols from a plurality of sequences of one or more graphic symbols, one or more sequences of the plurality of sequences including one or more ideographs, said method comprising the steps of:
- displaying on a display the plurality of sequences, each of the plurality of sequences having a common characteristic and each associated respectively with a sound indicator;
- matching a sound to any one of the plurality of sound indicators; and

selecting the sequence of the plurality of sequences associated with the matched sound indicator.

53. The method of claim 52 wherein the sound is not a phonetic representation of the sequence associated with the matched sound indicator.
54. The method of claim 52 wherein the sound indicator is non-alphanumeric.
55. The method of claim 54 wherein the sound indicator is a hue.
56. The method of claim 52 further comprising the step of indicating the association of each of the plurality of sequences with the associated sound indicator.
57. The method of claim 52 wherein each of the sequences belongs to any one of the Chinese language, Japanese language, Korean language, Picture Communication Symbols symbol set, Rebus symbol set, Picsyms symbol set, Pictogram Ideogram Communication Symbols symbol set, Yerkish symbol set, Blissymbolics symbol set, and a set of depictions of the signs of a manual sign language.
58. An apparatus for selecting a menu option from a plurality of menu options. said apparatus comprising:
- (a) a display area;
  - (b) means for at least partially delimiting a plurality of selectable regions, each of the selectable regions outside the display area and each associated respectively with a menu option;
  - (c) movement related signal receiving means for receiving a movement related signal indicating a location with respect to the display area; and
  - (d) selection means for selecting, in response to a selection event associated with the selectable region intersected by the location, the menu option associated with the intersected selectable region.
59. The apparatus of claim 58 wherein the selection event includes a switch operation at or near the time the intersection occurs.

60. The apparatus of claim 58 further comprising means for indicating the menu option associated with each selectable region.
61. The apparatus of claim 58 further comprising means for indicating which one of the selectable regions is intersected by the location.
62. The apparatus of claim 58 further comprising location indication means for indicating the location of each selectable region.
63. The apparatus of claim 62 wherein the location indication means further comprises means for displaying each menu option on the display area, wherein the location of each displayed menu option indicates the location of the associated selectable region.
64. The apparatus of claim 62 where the location indication means includes means for displaying at least part of each selectable region on the display area.
65. The apparatus of claim 58 wherein the selection event includes a switch operation; and wherein the selection means further comprises switch operation receiving means for receiving a signal indicating the switch operation.
66. The apparatus of claim 58 wherein the selection means is at least partially disabled in response to a first selection event.
67. The apparatus of claim 66 wherein the selection means, in response to a second selection event, is restored to the functionality it had prior to the first selection event.
68. The apparatus of claim 58 wherein all or all but one of the selectable regions are partially delimited.
69. The apparatus of claim 68 wherein one of the selectable regions is completely delimited.
70. The apparatus of claim 68 further comprising a computer system including display means for displaying at least part of the output of an application program executable on the computer system in the region on the display area and wherein at least one of the menu options

represents an input to the application program.

71. An apparatus for selecting a menu option from a plurality of menu options, said apparatus comprising:
- 5 (a) a display area;
- (b) means for at least partially delimiting a plurality of selectable regions, each of the selectable regions outside the display area and each associated respectively with a menu option;
- 10 (c) movement related signal receiving means for receiving a movement related signal indicating successive locations with respect to the display area; and
- (d) selection means, responsive to a first dwell event associated with any one of the selectable regions outside the display area, for selecting the menu option associated with the selectable region outside the display area associated with the first dwell event.
- 15 72. The apparatus of claim 71 further comprising a pointer, responsive to the movement of a body member of an operator other than either of the operator's eyes, for generating the movement related signal.
73. The apparatus of claim 71 wherein the selection means is responsive to a plurality of periods of intersection, each of two or more of the successive locations and the intersected selectable regions.
- 20 74. The apparatus of claim 71 wherein some of the selectable regions are not completely visible.
75. The apparatus of claim 71 wherein at most one of the selectable regions is adjacent the display area.
- 25 76. The apparatus of claim 71 wherein each of the successive locations is relative to a predetermined location on the display area or to a previous location of the successive locations.
- 30 77. The apparatus of claim 71 wherein the first dwell event includes a first quantity equalling or exceeding a predetermined quantity, the first quantity being a function of the durations of one or more successive periods of intersection of two or more of the successive locations and

one of the selectable regions; and wherein the selectable region associated with the first dwell event is the intersected selectable region.

5 78. The apparatus of claim 71 wherein the first dwell event includes a first quantity equalling or exceeding a predetermined quantity, the first quantity being a function of:

(1) the durations of one or more successive periods of intersection of two or more of the successive locations and a first one of the selectable regions; and

(2) the durations of one or more successive periods of intersection of two or more of the successive locations and a second one of the selectable regions; and

10 wherein the selectable region associated with the first dwell event is the selectable region intersected by one of the successive locations when the first dwell event occurs.

79. The apparatus of claim 71 further comprising a plurality of selectable regions on the display area, each associated respectively with one of the selectable regions outside the display area;  
15 and wherein the selection means is further operative, responsive to a second dwell event associated with any one of the selectable regions on the display area, to select the menu option associated with the selectable region outside the display area associated with the selectable region on the display area associated with the second dwell event.

20 80. The apparatus of claim 79 wherein the selection means is further operative, responsive to a first quantity equalling or exceeding a predetermined quantity, the first quantity being a function of:

(a) the durations of one or more successive periods of intersection of two or more of the successive locations and one of the selectable regions on the display area; and

25 (b) the durations of one or more successive periods of intersection of two or more of the successive locations and the selectable region outside the display area associated with the intersected selectable region on the display area;

to select the menu option associated with the selectable region outside the display area.

30 81. The apparatus of claim 79 wherein each of one or more of the selectable regions on the display area is adjacent the associated selectable region outside the display area.

82. The apparatus of claim 79 wherein each of one or more of the selectable regions on the display area indicates the location of the associated selectable region outside the display area.

83. The apparatus of claim 79 wherein the plurality of selectable regions on the display area together at least partially circumscribe a region on the display area.
- 5 84. The apparatus of claim 83 wherein the selection means further includes means for indicating the remaining dwell time required to select the intersected selectable region.
85. The apparatus of claim 83 wherein the movement related signal is responsive to the movement of a body member of an operator having impaired ability to sense the position of  
10 the body member and the apparatus further comprises tactile indication means for indicating tactilely to the operator the position of the body member.
86. The apparatus of claim 83 wherein the selection means further includes means for indicating on the display area the location of one of the successive locations located outside the display  
15 area.
87. The apparatus of claim 83 wherein the selection means further includes means for indicating on the display area the distance between one of the successive locations located outside the display area and the point on the display closest thereto.  
20
88. In a human interface system including a display whereon a first cursor may be displayed and moved responsive to successive locations indicated by a movement related signal, an apparatus for selecting a menu option associated with an overshoot selectable region on the display, said apparatus comprising:  
25
- (a) means for displaying a plurality of selectable regions within a first polygon intersecting the display, each selectable region associated respectively with a menu option, each selectable region adjacent a side of the first polygon and the plurality of selectable regions together at least partially circumscribing a region on the display;
- (b) movement related signal receiving means for receiving the movement related signal  
30 indicating the successive locations; and
- (c) control means for
- (1) moving the first cursor within the first polygon responsive to the successive locations indicated by the movement related signal;
- (2) confining at least part of the first cursor to the first polygon; and

- (3) in response to a first quantity equalling or exceeding a predetermined quantity, the first quantity being a function of the durations of one or more successive periods of intersection of the first cursor and one of the selectable regions, selecting the menu option associated with the intersected selectable region.

5

89. The apparatus of claim 88 wherein the first polygon is located on the display.

90. The apparatus of claim 89 wherein at least one of the selectable regions intersects the at least partially circumscribed region.

10

91. The apparatus of claim 89 wherein the control means is further operative to confine at least part of the first cursor to a second polygon on the display.

92. The apparatus of claim 91 wherein the control means is further operative to switch, responsive to an intersection of the first cursor and one of the selectable regions, from confining at least part of the first cursor to the first polygon to confining at least part of the first cursor to the second polygon .

15

93. The apparatus of claim 91 wherein the control means is further operative to switch, responsive to a distance between two of the successive locations, from confining at least part of the first cursor to the first polygon to confining at least part of the first cursor to the second polygon

20

94. The apparatus of claim 91 wherein the control means is further operative to switch, responsive to an angle indicated by three of the successive locations, from confining at least part of the first cursor to the first polygon to confining at least part of the first cursor to the second polygon

25

95. The apparatus of claim 91 wherein the first polygon intersects the second polygon.

30

96. The apparatus of claim 95 wherein the first polygon includes all of the area of the second polygon.

97. The apparatus of claim 89 wherein the selection of the control means is further responsive to the proximity of one of the successive locations indicated by the movement related signal to the location of the first cursor.
- 5 98. The apparatus of claim 89 wherein the selection of the control means is further responsive to the proximity of one of the successive locations indicated by the movement related signal to the intersected selectable region.
99. The apparatus of claim 89 wherein the first polygon has at least five sides.
- 10 100. The apparatus of claim 89 wherein at least one of the plurality of selectable regions is associated with an icon on the display.
101. The apparatus of claim 100 wherein the icon represents one of a sign of a manual sign  
15 language, a location relative to a human body, a movement of a manual sign language a topic of conversation, a sentence, a desired direction of movement of a second cursor on the display, a sequence of one or more graphics including an ideograph, and a symbol of a symbol set.
- 20 102. An apparatus for selecting a submenu option from a menu hierarchy, said apparatus comprising:
- (a) a display area;
  - (b) a menu comprising a plurality of menu options, at least one of the menu options associated with a submenu comprising a plurality of submenu options;
  - 25 (c) means for at least partially delimiting:
    - (1) a plurality of first selectable regions, each of the first selectable regions associated respectively with one of the menu options and each of the first selectable regions including a first subregion adjacent the display area and a first subregion on the display area, the plurality of the first subregions on the display area together at least partially circumscribing a first region on the display area;
    - 30 and
    - (2) a plurality of second selectable regions, each of the second selectable regions associated respectively with one of the submenu options and each of the second selectable regions including a second subregion adjacent the display area and a

second subregion on the display area, the plurality of the second subregions on the display area together at least partially circumscribing a second region on the display area;

- 5 (d) movement related signal receiving means for receiving a movement related signal indicating successive locations with respect to the display area; and
- (e) selection means for selecting, in response to a first dwell event, the menu option associated with the first selectable region intersected by one of the successive locations indicated by the movement related signal, the menu option being one of the menu options associated with a submenu, and for selecting, in response to a second dwell
- 10 event, the submenu option associated with the second selectable region intersected by one of the successive locations indicated by the movement related signal.

103. The apparatus of claim 102 wherein one of the menu options represents a group of characters and wherein a first one of the submenu options represents a first one character of the group

15 of characters.

104. The apparatus of claim 103 wherein each character of the group of characters has one of:
- (a) an extension at least a predetermined distance above the baseline of the group of characters;
- 20 (b) an extension below the baseline of the group of characters;
- (c) lack of the characteristic described in (a); and
- (d) lack of the characteristic described in (b).

25 105. The apparatus of claim 103 wherein the distance on the display area between the first subregion on the display area associated with the menu option representing the group of characters and the second subregion on the display area associated with the submenu option representing the first one character of the group of characters is responsive to the frequency of use of the first one character.

30

106. The apparatus of claim 103 wherein:
- (a) a second one of the submenu options represents a second one character of the group of characters;
- (b) the first one character is more frequently used than the second one character; and

- (c) the distance on the display area between the first subregion on the display area associated with the menu option representing the group of characters and the second subregion associated with the submenu option representing the first one character of the group of characters is less than the distance on the display area between the first subregion on the display area associated with the menu option representing the group of characters and the second subregion on the display area associated with the submenu option representing the second one character of the group of characters.
107. The apparatus of claim 103 wherein the position of a character of the group of characters indicates the position of the second subregion on the display area associated with the submenu option representing the first one character of the group of characters.
108. An apparatus for selecting a menu option from a plurality of menu options, said apparatus comprising:
- (a) a surface;
  - (b) means for delimiting a plurality of selectable regions on the surface, each of the selectable regions associated respectively with a menu option, the plurality of selectable regions together at least partially circumscribing a region on the surface;
  - (c) a pointer, responsive to the movement of a one of an operator's limbs, digits and head, for indicating successive locations on the surface; and
  - (d) selection means for selecting, in response to a dwell event, the menu option associated with the selectable region intersected by one of the successive locations indicated by the pointer.
109. An apparatus for selecting a menu option from a plurality of menu options, said apparatus comprising:
- (a) means for displaying a plurality of selectable regions on a display area, each of the selectable regions associated respectively with a menu option, the plurality of selectable regions together at least partially circumscribing a region on the display area;
  - (b) movement related signal receiving means for receiving a movement related signal indicating successive locations on the surface; and
  - (c) in response a quantity equalling or exceeding a predetermined quantity, the quantity being a function of the durations of a plurality of successive periods of intersection of

two or more of the successive locations and one of the selectable regions, selection means for selecting the menu option associated with the intersected selectable region.

110. An apparatus for selecting an option from a menu, said apparatus comprising:
- 5 (a) cursor movement means for receiving a movement related signal and for moving a cursor on a display responsive to the received movement signal;
- (b) delimit means for delimiting on the display a first plurality of regions and a second plurality of selectable regions, each of the second plurality of selectable regions associated respectively with a menu option; the first plurality of regions together at
- 10 least partially circumscribing a first region on the display; and
- (c) selection means, responsive only to an intersection of the cursor and a first one of the first plurality of regions and thereafter to a first selection event associated with one of the second plurality of selectable regions, for selecting the menu option associated with the selectable region associated with the first selection event.
- 15
111. The apparatus of claim 110 further comprising means for receiving a switch operation signal; and wherein the delimit means includes means for displaying the first plurality of regions responsive to the received switch operation signal.
- 20
112. The apparatus of claim 110 wherein the second plurality of selectable regions together at least partially circumscribing the first region on the display.
- 113 The apparatus of claim 110 further comprising a third plurality of selectable regions, each of the third plurality of selectable regions associated respectively with a menu option; and
- 25 wherein the selection means is further responsive to an intersection of the cursor and a second one of the first plurality of regions and thereafter to a second selection event associated with one of the third plurality of selectable regions, for selecting the menu option associated with the selectable region associated with the second selection event.
- 30
114. The apparatus of claim 110 wherein the selection means includes means for receiving a switch operation signal; and wherein the first selection event includes:
- (1) an intersection of the cursor and the selectable region associated with the second selection event; and
- (2) at or near the time the intersection occurs, receipt of the switch operation signal.

115. In a human interface system wherein a body member of an operator may indicate successive locations with respect to a display, a menu option selector for selecting a menu option from a plurality of menu options, said menu option selector comprising:

- 5 (a) the display having thereon a first plurality of selectable regions, each of the first plurality of selectable regions associated respectively with one of the menu options;
  - (b) means for at least partially delimiting a second plurality of selectable regions, each of the second plurality of selectable regions located outside the display and each associated respectively with one of the first plurality of selectable region;
  - 10 (c) in response to a first quantity equalling or exceeding a predetermined quantity, the first quantity being a function of:
    - (1) the durations of one or more successive periods of intersection of two or more of the successive locations and one of the selectable regions on the display area;
    - and
    - 15 (2) the durations of one or more successive periods of intersection of two or more of the successive locations and the selectable region outside the display area associated with the one of the selectable regions on the display area;
- a selector for selecting the menu option associated with the one of the selectable regions on the display area.

20

116. The apparatus of claim 115 wherein the plurality of the subregions on the display together at least partially circumscribing a region on the display.

117. In a human interface system wherein a body member of an operator may indicate a location on a surface, a menu option selector comprising:

25

- (a) the surface including a display area, the display area having thereon a plurality of selectable regions, each of the selectable regions associated respectively with a menu option, the plurality of selectable regions together at least partially circumscribing a region on the display area;
- 30 (b) a clipper for generating, in response to the location indicated by the body member of the operator indicating a location outside the display area, a clipped location indicative of a location on the display area; and
- (c) a selector for selecting, in response to a selection event, the menu option associated with the selectable region intersected by the clipped location.

118. In a human interface system wherein a body member of an operator may indicate a location on a surface, a menu option selector comprising:

- 5 (a) the surface including a display area, the display area having thereon a plurality of selectable regions, each of the selectable regions associated respectively with a menu option, the plurality of selectable regions together at least partially circumscribing a region on the display area;
- (b) a confiner for confining the location indicated by the body member of the operator to the display area; and
- 10 (c) a selector for selecting, in response to a selection event, the menu option associated with the selectable region intersected by the location indicated by the body member of the operator.

119. The menu option selector of claim 117 or 118 wherein each of the plurality of selectable  
15 regions is adjacent an edge of the display area.

120. In a human interface system wherein a body member of an operator may indicate successive locations on a surface, a menu option selector comprising:

- 20 (a) a detector area on the surface and including a plurality of selectable regions, each of the selectable regions associated respectively with a menu option;
- (b) a confiner for confining the location indicated by the body member of the operator to the detector area; and
- (c) a selector for selecting, in response to a dwell event associated with any one of the  
25 selectable regions, the menu option associated with the selectable region associated with the dwell event.

121. The menu option selector of claim 120 wherein each of the plurality of selectable regions is adjacent an edge of the detector area.

30

122. For use with a general purpose computer system including a display on which a cursor may be displayed, the general purpose computer system being capable of executing an application program, an apparatus comprising:

- (a) a medium readable by the general purpose computer system; and

- (b) a program, stored on the medium and executable by the general purpose computer system, for:
- (1) displaying a plurality of selectable regions within a polygon on the display, each selectable region adjacent a side of the polygon, one or more of the selectable regions each associated respectively with a sequence of one or more characters, the plurality of selectable regions together at least partially circumscribing a region on the display;
  - (2) receiving a movement related signal and moving at least part of the cursor only within the polygon responsive to the movement related signal; and
  - (3) in response to a first quantity equalling or exceeding a predetermined quantity, the first quantity being a function of the durations of one or more successive periods of intersection of the cursor and one of the one or more selectable regions, inputting the sequence of one or more characters associated with the intersected selectable region to the application program.

15

123. A data entry system including a computer system on which may be executed an application program, said data entry comprising:

- (a) the computer system including a display;
- (b) a pointer selected from the group consisting of a (1) mouse; (2) trackball; (3) joystick; (4) stylus and graphics tablet; (5) lightpen; (6) thumb wheel; (7) touch screen; (8) head pointer; and (9) intraoral pointer, the pointer coupled to the computer system; and
- (c) program means executable on the computer system for:
  - (1) displaying a plurality of selectable regions within a polygon on the display, each selectable region adjacent a side of the polygon, the plurality of selectable regions together at least partially circumscribing a region on the display;
  - (2) moving a cursor within the polygon responsive to movement of the pointer; and
  - (3) in response to a selection event and an intersection of the cursor and a selectable region associated with an input for the application program, inputting the input to the application program.

20

25

30

124. A computer access system for an operator having impaired motor capability, said computer access system including a computer system on which may be executed a computer program, said computer access system comprising:

- (a) the computer system including a display;
- (b) program means executable on the computer system for:
  - (1) displaying a plurality of selectable regions within a polygon on the display, each selectable region adjacent a side of the polygon, the plurality of selectable regions together at least partially circumscribing a region on the display;
  - (2) receiving a movement related signal and moving at least part of a cursor only within the polygon responsive to the movement related signal; and
  - (3) in response to a selection event and an intersection of the cursor and a selectable region associated with an input for the computer program, inputting the input to the computer program.

125. A speech synthesis system comprising:

- (a) a display on which may be displayed a plurality of selectable regions within a polygon on the display, each selectable region adjacent a side of the polygon and one or more of the selectable regions associated respectively with a sequence of one or more characters, the plurality of selectable regions together at least partially circumscribing a region on the display;
- (b) a speech synthesizer; and
- (c) control means for:
  - (1) receiving a movement related signal and moving a cursor within the polygon responsive to the movement related signal;
  - (2) repetitively, in response to a selection event and an intersection of the cursor and one of the selectable regions associated with one of the one or more sequences of one or more letters, appending the sequence associated with the intersected selectable region to at least one previously selected sequence; and
  - (3) speaking, by means of the speech synthesizer, the word spelled by the appended sequences.

126. A device controller comprising:

- (a) means for displaying a plurality of selectable regions within a polygon on a surface, each selectable region adjacent a side of the polygon and each selectable region associated respectively with a device control function, the plurality of selectable regions together at least partially circumscribing a region of the polygon;

- (b) signal generating means coupled to a device for generating a device control signal; and
- (c) control means for:

- (1) receiving a movement related signal and moving at least part of a cursor only within the polygon in response to the received movement related signal; and
- (2) in response to a selection event, generating a device control signal corresponding to the device control function associated with the one of the plurality of selectable regions intersected by the cursor.

127. The device controller of claim 126 wherein the device includes any one of a wheelchair, a household appliance, an appliance for use in an office, a workstation, a robot, and a computer peripheral.

128. For use with a surface comprising a display area, a method of selecting a menu option from a plurality of menu options, said method comprising the steps of:

at least partially delimiting a plurality of selectable regions, each of the selectable regions associated respectively with a menu option and each of the selectable regions including an invisible subregion outside the display area and a visible subregion on the display area, the plurality of visible subregions together at least partially circumscribing a region on the display area;

receiving a movement related signal indicating successive locations with respect to the display area; and

selecting, in response to a dwell event associated with one of the selectable regions, the menu option associated with the selectable region associated with the dwell event.

129. For use with a human interface system wherein a body member of an operator may indicate successive locations on a surface, the surface including a display area, the display area having thereon a plurality of selectable regions, each of the selectable regions associated respectively with a menu option and the plurality of selectable regions together at least partially circumscribing a region on the display area, a method of selecting a menu option from a plurality of menu options, said method comprising the steps of:

confining each of the successive locations to the display area; and

selecting, in response to a dwell event associated with one of the selectable regions, the menu option associated with the selectable region associated with the dwell event.

5

130. A method of speaking using a speech synthesis system including a display and a speech synthesizer, said method comprising the steps of:

10

displaying a plurality of selectable regions within a polygon on the display, each selectable region adjacent a side of the polygon and one or more of the selectable regions associated respectively with a sequence of one or more characters, the plurality of selectable regions together at least partially circumscribing a region on the display;

15

receiving a movement related signal and moving at least part of a cursor only within the polygon responsive to the movement related signal;

repetitively:

20

(i) in response to a first quantity equalling or exceeding a predetermined quantity, the first quantity being a function of the durations of one or more successive periods of intersection of the cursor and one of the one or more selectable regions, selecting the sequence associated with the intersected selectable region; and

25

(ii) appending the selected sequence to at least one previously selected sequence; and

speaking, by means of the speech synthesizer, the word spelled by the appended sequences.

30

131. A method of inputting data to a computer program for an operator having impaired motor capability, said method comprising the steps of:

displaying a plurality of selectable regions within a polygon on a display, each

selectable region adjacent a side of the polygon and each selectable region associated respectively with an input for the computer program, the plurality of selectable regions together at least partially circumscribing a region on the display:

5 receiving a movement related signal and moving at least part of a cursor only within the polygon responsive to the movement related signal; and

10 in response to a first quantity equalling or exceeding a predetermined quantity, the first quantity being a function of the durations of one or more successive periods of intersection of the cursor and one of the selectable regions, inputting the input associated with the intersected selectable region to the computer program.

132. An apparatus for indicating dwell time comprising:

- 15 (a) a surface with respect to which a region may be at least partially delimited;
- (b) movement receiving means for receiving a movement related signal indicating a first location intersecting the region and, at a later time, a second location intersecting the region; and
- (c) indicating means for indicating at least the difference between the time the second location occurs and the time the first location occurs.

20 133. The apparatus of claim 132 wherein the indicating means includes means for determining the difference between the time the second location occurs and the time the first location occurs.

25 134. The apparatus of claim 132 wherein the indicating means includes an indicator and means for modifying the appearance of the indicator.

135. The apparatus of claim 132 wherein the region intersects the surface.

136. The apparatus of claim 132 wherein the region is adjacent the surface.

30 137. The apparatus of claim 132 wherein the movement related signal further indicates, at a time later than the time the second location occurs, a third location not intersecting the region and the indicating means is further operative to indicate the non-intersection of the third location and the region.

138. The apparatus of claim 132 wherein the movement related signal further indicates, at a time later than the time the second location occurs, a third location not intersecting the region and, at a later time, indicates a fourth location not intersecting the region and the indicating means  
5 is further operative to indicate at least the difference between the time the fourth location occurs and the time the third location occurs.
139. The apparatus of claim 132 wherein the indicating means includes means for producing an output signal which varies in at least one way as the difference between the time the second  
10 location occurs and the time the first location occurs increases and varies in at least the opposite way as the difference between the time the fourth location occurs and the time the third location occurs increases.
140. An apparatus for indicating dwell time comprising:  
15 (a) a pointer;  
(b) a detector; and  
(c) an indicator for indicating at least the duration of a period the pointer indicates the detector.
- 20 141. The apparatus of claim 140 wherein the indication of the duration of the period of detection includes a visible signal.
142. The apparatus of claim 140 wherein the indication of the duration of the period of detection includes an audible signal.  
25
143. The apparatus of claim 140 wherein the indication of the duration of the period of detection includes a tactile signal.
144. An apparatus for indicating the remaining dwell time required to select a selectable region, said apparatus comprising:  
30 (a) a surface with respect to which the selectable region may be at least partially delimited;  
(b) movement receiving means for receiving a movement related signal indicating successive locations with respect to the surface; and

(c) indicating means for modifying in a first manner the appearance of a first indicating region on the surface responsive to a period of intersection of two or more of the successive locations and the selectable region not equalling or exceeding a predetermined period and for modifying in a second manner the appearance of a second indicating region on the surface responsive to a period of intersection of two or more of the successive locations and the selectable region equalling or exceeding the predetermined period.

145. The apparatus of claim 144 wherein the modification in the first manner includes a slight modification and the modification in the second manner includes a marked modification.

146. The apparatus of claim 144 wherein the modification in the first manner includes a modification in brightness.

147. The apparatus of claim 144 wherein the modification in the second manner includes a modification in hue.

148. The apparatus of claim 144 wherein the first indicating region intersects the second indicating region.

149. The apparatus of claim 144 wherein one of the first and second indicating regions intersects the selectable region.

150. The apparatus of claim 144 wherein one of the first and second indicating regions is coterminous with the selectable region.

151. An apparatus for indicating dwell time comprising:

- (a) a surface with respect to which a plurality of regions may be at least partially delimited;
- (b) movement receiving means for receiving a movement related signal indicating a first location intersecting any one of the plurality of regions and, at a later time, a second location intersecting the region intersected by the first location; and
- (c) a plurality of indicators, each associated respectively with a region, for indicating at

least the difference between the time the second location occurs and the time the first location occurs.

152. The apparatus of claim 151 wherein each indicator is adjacent its associated region.

5

153. The apparatus of claim 151 wherein each indicator intersects its associated region.

154. An apparatus for selecting a menu option from a plurality of menu options, said apparatus comprising:

- 10
- (a) a surface with respect to which a plurality of selectable regions may be at least partially delimited, each selectable region associated respectively with a menu option;
  - (b) movement receiving means for receiving a movement related signal indicating successive locations with respect to the surface; and
  - (c) selection means for selecting, in response to a dynamic dwell event, the menu option
- 15
- associated with the selectable region intersected by the location of the successive locations whose occurrence triggers the dynamic dwell event.

155. In a human interface system wherein a body member of an operator may indicate successive locations with respect to a surface, a menu option selector comprising:

- 20
- (a) the surface with respect to which a selectable region may be at least partially delimited, the selectable region associated with a menu option;
  - (b) a detector for detecting the successive locations; and
  - (c) responsive to:
    - (1) the duration of a first period during which two or more of the successive
- 25
- locations intersect the selectable region;
  - (2) the duration of a second period, occurring after the first period, during which two or more of the successive locations do not intersect the selectable region; and
  - (3) the duration of a third period, occurring after the second period, during which two or more of the successive locations intersect the selectable region;
- 30
- a selector for selecting the menu option.

156. A device controller comprising:

- (a) display means for displaying a plurality of selectable regions on a surface, each selectable region associated respectively with a device control function;

- (b) movement receiving means for receiving a movement related signal indicating successive locations on the surface;
  - (c) indicating means for indicating at least the duration of a period of intersection of two or more of the successive locations indicated by the movement related signal and a selectable region; and
  - (d) initiation means, responsive to a dwell event, for initiating the control function associated with the intersected selectable region.
157. The device controller of claim 156 further comprising a controlled device, responsive to the initiation means, for performing the device control function.
158. The device controller of claim 157 wherein the controlled device includes one of a household appliance and a motorized wheelchair.
159. A computer access device for an operator having impaired motor control, said device comprising:
- (a) a computer system, including a display on which may be displayed a plurality of selectable regions, each of the selectable regions associated respectively with a sequence of one or more characters, and on which display a moveable cursor may be displayed and then moved responsive to a movement related signal, the computer system being further capable of executing an application program operative to accept signals representing any of the plurality of sequences of one or more characters; and
  - (b) an access program, for execution on the computer system, for indicating at least the duration of a period of intersection of the cursor and any one of the one or more selectable regions and for inputting to the application program signals representing the sequence of one or more characters associated with the intersected selectable region in response to the period of intersection of the cursor and the intersected selectable region equalling or exceeding a predetermined period.
160. For use with a general purpose computer system including a display with respect to which may be at least partially delimited a plurality of selectable regions, each of the selectable regions associated respectively with a sequence of one or more characters, wherein the general purpose computer system is capable of receiving a movement related signal indicating successive locations with respect to the display, and wherein the general purpose

computer system is capable of executing an application program;

- (a) a medium readable by the general purpose computer system; and
- (b) a program, stored on the medium and executable by the general purpose computer system, for:

- (1) indicating at least the duration of a period of intersection of two or more of the successive locations and any one of the selectable regions; and
- (2) passing to the application program the sequence of one or more characters associated with the intersected selectable region in response to the duration of the period of intersection equalling or exceeding a predetermined period.

161. For use with a processing unit,

- (a) said processing unit coupled to a display on which may be displayed a plurality of selectable regions, each region associated respectively with a sequence of one or more characters;
- (b) said processing unit being capable of receiving a movement related signal indicating successive locations on the display;
- (c) said processing unit being capable of executing an application program;

an access program, executable on the processing unit, for an operator having impaired motor control, said access program operative to indicate at least the duration of a period of intersection of two or more of the successive locations and an intersected selectable region and to pass to the application program the sequence of one or more characters associated with the intersected selectable region in response to the duration of the period of intersection equalling or exceeding a predetermined period.

162. The computer access device of claim 161 wherein the access program and the application program include at least some common code.

163. For use with a computer system, a computer access device for an operator having impaired motor control, said device comprising:

- (a) a pointer;
- (b) a detector associated with a sequence of one or more characters;
- (c) an indicator for indicating at least the duration of a period the pointer indicates the detector; and

- (d) a processing unit coupled to the computer system for inputting to the computer system, in response to a dwell event, signals representing the sequence of one or more characters associated with the detector.

5 164. A speech synthesis system comprising:

- (a) a display with respect to which may be delimited a plurality of selectable regions, each of the selectable regions associated respectively with a sequence of one or more characters;
- (b) a speech synthesizer; and
- 10 (c) control means for
  - (1) receiving a movement related signal indicating successive locations with respect to the surface;
  - (2) repetitively
    - 15 (a) indicating the duration of a first period of intersection of two or more of the successive locations and a first one of the selectable regions; and
    - (b) in response to the duration of a second period of intersection of two or more of the successive locations and the first one of the selectable regions equalling or exceeding a predetermined period, appending the sequence associated with the first one of the selectable regions to at least one
  - 20 previously selected sequence; and
  - (3) speaking, by means of the speech synthesizer, the word spelled by the appended sequences.

165. A speech synthesis system comprising:

- 25 (a) a display on which may be displayed a plurality of selectable regions, each selectable region associated respectively with a sequence of one or more characters;
- (b) a speech synthesizer; and
- (c) control means for:
  - (1) receiving a movement related signal indicating:
    - 30 (A) a first location intersecting any one of the plurality of selectable regions;
    - (B) at a time after the first location occurs, a second location intersecting the selectable region intersected by the first location;
    - (C) at a time after the second location occurs, a third location not intersecting the selectable region intersected by the first location;

- (D) at a time after the third location occurs, a fourth location not intersecting the selectable region intersected by the first location;
- (E) at a time after the fourth location occurs, a fifth location intersecting the selectable region intersected by the first location: and
- 5 (F) at a time after the fifth location occurs, a sixth location intersecting the selectable region intersected by the first location:
- (2) repetitively:
- (A) responsive to the difference between the time the second location occurs and the time the first location occurs, increasing the brightness of the selectable region;
- 10 (B) responsive to the difference between the time the fourth location occurs and the time the third location occurs, decreasing the brightness of the selectable region: and
- (C) responsive to a quantity that is a function of:
- 15 (i) the difference between the time the second location occurs and the time the first location occurs;
- (ii) the difference between the time the fourth location occurs and the time the second location occurs; and
- (iii) the difference between the time the sixth location occurs and the time the fifth location occurs;
- 20
- equalling or exceeding a predetermined quantity, appending the sequence associated with the selectable region to at least one previously selected sequence: and
- 25 (3) speaking, by means of the speech synthesizer, the word spelled by the appended sequences.

166. A data entry system comprising:

- 30 (a) a display having thereon a plurality of selectable data entry items and a region for indicating the number of units of the data entry item selected;
- (b) a plurality of detectors, each associated respectively with one of the selectable data entry items;
- (c) a pointer for emitting signals directed at the data entry items: and
- (d) control means for controlling the operation of said data entry system, the control

means including:

- (1) first indicating means for producing signals in response to the signals falling on the detectors, said first indicating means giving a first indication of the period of time that the pointer has been directed to a first one of the data entry items;
- 5 (2) second indicating means for producing signals in response to the signals falling on the detectors, said second indicating means giving a second indication that the pointer has been directed to a second one of the data entry items for at least a predetermined period of time and that the second one of the data entry items is selected for entry into the data entry system; and
- 10 (3) third indicating means for indicating in the region the number of units of the data entry item selected.

167. A order entry system comprising:

- 15 (a) a display having thereon a plurality of selectable order entry items, a first region for indicating the number of units of the order entry item selected and a second region for indicating the total monetary value of the units selected;
- (b) a plurality of detectors, each associated respectively with one of the selectable order entry items;
- (c) a pointer for emitting signals directed at the order entry items; and
- 20 (d) control means for controlling the operation of said order entry system, the control means including
  - (1) first indicating means for producing signals in response to the signals falling on the detectors, said first indicating means giving a first indication of the duration of the period that the pointer has been directed to a first one of the order entry
  - 25 items;
  - (2) second indicating means for producing signals in response to the signals falling on the detectors, said second indicating means giving a second indication that the pointer has been directed to a second one of the order entry items for at least a predetermined period of time and that the second one of the order entry items
  - 30 is selected for entry into the order entry system;
  - (3) third indicating means for indicating in the first region the number of units of the order entry item selected;
  - (4) totaling means for totaling the monetary value of the units selected; and
  - (5) fourth indicating means for indicating in the second region the total monetary

value of the units selected.

5 168. The order entry system of claim 167 wherein the first indicating means further includes third indicating means for giving a third indication of the duration of the period that the pointer is not directed to an order entry item to which it was previously directed.

10 169. The order entry system of claim 167 wherein the display further includes a pictorial representation for at least some of the order entry items and wherein the detectors are located within each pictorial representation.

170. The order entry system of claim 169 wherein the pictorial representation is in the form of a food item at a fast-food restaurant.

15 171. The order entry system of claim 167 wherein the pointer includes:  
(a) an infrared light source; and  
(b) a lens for producing a narrow beam of light in cooperation with the infrared light source.

20 172. The order entry system of claim 167 further comprising a stationary housing for housing the pointer, said housing positioned relative to the display to enable a person using the order entry system and seated in a vehicle to pick up the pointer, use it, and return it to the stationary housing while seated in the vehicle.

25 173. An apparatus for selecting a menu option from a plurality of menu options, said apparatus comprising:  
(a) a surface including a plurality of detectors each associated respectively with a menu option;  
(b) a pointer operative to emit energy detectable by each of the plurality of detectors; and  
(c) responsive to:  
30 (1) the duration of a first period during which a particular detector detects energy emitted by the pointer above a first threshold;  
(2) the duration of a second period, occurring after the first period, during which the particular detector does not detect energy emitted by the pointer above a second threshold; and

- (3) the duration of a third period, occurring after the second period, during which the particular detector detects energy emitted by the pointer above a third threshold;  
a selector for selecting the menu option associated with the particular detector.

5 174. The apparatus of claim 173 wherein the selector selects the menu option associated with the particular detector in response to the sum of a multiple of the duration of the first period and a multiple of the duration of the third period minus a multiple of the duration of the second period equalling or exceeding a predetermined quantity.

10 175. An apparatus for inputting words, said apparatus comprising:

- (a) a display with respect to which may be delimited a selectable region associated with a word;
- (b) word receiving means for receiving a signal representing the word; and
- (c) control means for:

- 15 (1) receiving a movement related signal indicating successive locations with respect to the surface;
- (2) indicating the duration of a period of intersection of two or more of the successive locations and the selectable region; and
- (3) inputting, in response to the period of intersection equalling or exceeding a  
20 predetermined period, the signal representing the word to the word receiving means.

176. The apparatus of claim 175 wherein the word belongs to an ideographic language.

25 177. A method of indicating the remaining dwell time required to select a selectable region, said method comprising the steps of:

displaying the selectable region on a surface;

30 receiving a movement related signal indicating a first location intersecting the selectable region and, at a time after the first location occurs, a second location intersecting the selectable region; and

indicating the difference between the time the second location occurs and the time the first

location occurs.

178. The method of claim 177 further comprising the steps of:

5 receiving a movement related signal indicating, at a time after the time the second location occurs, a third location not intersecting the selectable region; and  
  
indicating the non-intersection of the third location and the selectable region.

10 179. The method of claim 178 further comprising the steps of:

receiving a movement related signal indicating, at a time after the time the third location occurs, a fourth location not intersecting the selectable region; and

15 indicating the difference between the time the fourth location occurs and the time the third location occurs.

180. In a human interface system including a surface on which may be displayed a cursor whose movement is responsive to a first movement related signal, and with respect to which surface  
20 may be at least partially delimited a plurality of selectable regions, each of the plurality of selectable regions associated respectively with a menu option, an apparatus for selecting any one of the plurality of menu options, said apparatus comprising:

(a) movement related signal receiving means for receiving the first movement related signal; and  
25 (b) selection means for selecting the menu option associated with the particular one of the plurality of selectable regions most nearly along a first cursor path indicated by a first cursor location and the first movement related signal in advance of an intersection of the cursor and the particular selectable region.

30 181. The apparatus of claim 180 wherein the movement related signal receiving means is further operative to receive a second movement related signal occurring subsequent to the first movement related signal; wherein the selection means is further operative to select the menu option associated with the specific one of the plurality of selectable regions most nearly along a second cursor path indicated by a second cursor location and the second movement

related signal in advance of an intersection of the cursor and the specific selectable region; wherein the first and second cursor paths are parallel; and wherein the particular selectable region is not the specific selectable region.

5 182. In a human interface system including a surface on which may be displayed a cursor whose movement is responsive to a first movement related signal, and with respect to which surface may be at least partially delimited a plurality of selectable regions, each of the plurality of selectable regions associated respectively with a menu option, an apparatus for selecting any one of the plurality of menu options, said apparatus comprising:

- 10 (a) movement related signal receiving means for receiving the first movement related signal; and
- (b) selection means for selecting the menu option associated with the particular one of the plurality of selectable regions most nearly along a first cursor path in response to an intersection of the cursor and said particular selectable region.

15

183. The apparatus of claim 180 or 182 further comprising means for indicating which one of the plurality of selectable regions is most nearly along the first cursor path.

184. The apparatus of claim 180 or 182 wherein the surface includes a display area and each of  
20 the plurality of selectable regions is adjacent an edge of the display area.

185. The apparatus of claim 180 or 182 wherein the plurality of selectable regions together at least partially circumscribes an area on the surface.

25 186. An apparatus for selecting an option from a menu, said apparatus comprising:

- (a) means for at least partially delimiting a plurality of selectable regions with respect to a surface, each of the plurality of selectable regions associated respectively with a menu option;
- (b) movement related signal receiving means for receiving a movement related signal; and
- 30 (c) control means for:
- (1) moving a cursor on the surface in response to the received movement related signal;
- (2) changing a selection threshold period responsive to a cursor path;
- (3) detecting an intersection of the cursor and any one of the plurality of selectable

regions; and

- (4) in response to the period of the intersection equalling or exceeding the selection threshold period, selecting the menu option associated with the intersected selectable region.

5

187. The apparatus of claim 186 wherein the control means is further operative to indicate the changed length of the selection threshold period.

10

188. The apparatus of claim 186 wherein one of the plurality of selectable regions has previously been selected and the amount of change to the selection threshold period varies in response to which one of the selectable regions has been previously selected.

189. The apparatus of claim 186 wherein the changed selection threshold period equals or exceeds a predetermined period.

15

190. The apparatus of claim 186 wherein one of the plurality of selectable regions has previously been selected and each location of the cursor in the cursor path is outside the previously selected selectable region.

20

191. The apparatus of claim 190 wherein each location of the cursor in the cursor path is at least a predetermined distance from the previously selected selectable region.

192. The apparatus of claim 190 wherein each location of the cursor in the cursor path occurs at least a predetermined period of time after the selection of the previously selected selectable region.

25

193. The apparatus of claim 186 wherein the amount of change to the selection threshold period varies in response to the distance between the intersected selectable region and the location of the cursor.

30

194. The apparatus of claim 186 wherein the amount of change to the selection threshold period varies in response to the difference between the time the intersection occurs and the time the location of the cursor occurs.

195. The apparatus of claim 186 wherein each of the plurality of selectable regions includes a subregion visible on the surface and an invisible subregion located outside the surface and wherein the plurality of visible subregions together at least partially circumscribes an area on the surface.
- 5
196. The apparatus of claim 186 wherein the movement related signal is responsive to the movement of a body member of an operator having impaired ability to sense the position of the body member and the apparatus further comprises tactile indication means for indicating with the body member tactilely to the operator the position of the body member.
- 10
197. The apparatus of claim 186 wherein one or more of the plurality of menu options represents any one of:
- (a) a prefix;
  - (b) an infix; and
  - 15 (c) a suffix;
- to be added to a root word.
198. An apparatus for selecting a menu option from a plurality of menu options, said apparatus comprising:
- 20
- (a) means for at least partially delimiting a plurality of selectable regions with respect to a surface, each of the plurality of selectable regions associated respectively with a menu option;
  - (b) movement related signal receiving means for receiving a movement related signal indicating successive locations on the surface; and
  - 25 (c) control means for:
    - (1) moving a cursor in a first manner on the surface in response to the movement related signal and thereafter detecting an intersection of the cursor and any one of the plurality of selectable regions;
    - (2) responsive to a first cursor path, moving the cursor in a second manner on the surface in response to the movement related signal, wherein the movement of the cursor in the second manner is attenuated relative to the movement of the cursor in the first manner; and
    - 30 (3) in response to the period of the intersection equalling or exceeding a selection threshold period, selecting the menu option associated with the intersected

selectable region.

- 5
199. The apparatus of claim 198 wherein the moving of the cursor in the second manner is further responsive to the intersection.
200. The apparatus of claim 199 wherein the moving of the cursor in the second manner is further responsive to a path indicated by successive locations occurring after the intersection.
- 10
201. The apparatus of claim 199 wherein the moving of the cursor in the second manner is further responsive to an angle of attack of the cursor path to the intersected selectable region.
202. The apparatus of claim 198 wherein the plurality of selectable regions together at least partially circumscribes an area on the surface.
- 15
203. The apparatus of claim 198 wherein the moving of the cursor in the second manner is further responsive to the velocity of the first cursor path.
204. The apparatus of claim 198 wherein the moving of the cursor in the second manner is further responsive to the acceleration of the first cursor path.
- 20
205. The apparatus of claim 198 wherein the moving of the cursor in the second manner is further responsive to the proximity of a cursor location in the first cursor path to the selectable region most nearly along the first cursor path.
- 25
206. In a human interface system including a first surface on which may be displayed a plurality of selectable regions each associated respectively with a menu option, and wherein a body member of an operator may indicate successive locations on a second surface, each location corresponding to a location on the first surface, a selection controller comprising:
- 30
- (a) a direction detector for determining a move direction of the body member responsive to two or more of the successive locations on the second surface; and
  - (b) a selector for selecting the menu option associated with the particular one of the plurality of selectable regions most nearly along a path on the first surface corresponding to the move direction of the body member, the selection occurring in advance of an intersection of any one of the locations on the first surface and the

particular selectable region.

207. In a human interface system including a first surface on which may be displayed a plurality of selectable regions each associated respectively with a menu option, and wherein a body member of an operator may indicate successive locations on a second surface, each location corresponding to a location on the first surface, a selection controller comprising:
- 5
- (a) a direction detector for determining a move direction of the body member responsive to two or more of the successive locations on the second surface; and
  - (b) a selector for selecting the menu option associated with the particular one of the
- 10
- plurality of selectable regions most nearly along a path on the first surface corresponding to the move direction of the body member, the selector being responsive to an intersection of one of the locations on the first surface and the particular selectable region.
- 15
208. In a human interface system including
- a first surface on which may be displayed a plurality of regions each associated respectively with a menu option;
- wherein a body member of an operator may indicate successive locations on a second surface, each location corresponding to a location on the first surface; and
- 20
- wherein a particular one of the regions may be selected responsive to a period of intersection of two or more of the locations on the first surface and the particular region equalling or exceeding a selection threshold period;
- a selection threshold controller comprising:
- (a) a direction detector for determining a move direction of the body member responsive
- 25
- to two or more of the locations on the second surface; and
- (b) means for changing the selection threshold period responsive to the move direction of the body member.
209. The selection threshold controller of claim 208 further comprising a pointer for indicating
- 30
- with the body member successive locations on the second surface.
210. The selection threshold controller of claim 208 wherein the first surface includes the second surface.

211. The selection threshold controller of claim 208 wherein the second surface includes the first surface.
212. The selection threshold controller of claim 208 wherein the body member of the operator  
5 includes any one of the operator's shoulder, the operator's arm, the operator's elbow, the operator's wrist, the operator's hand, the operator's finger, the operator's thumb, the operator's leg, the operator's knee, the operator's ankle, the operator's foot, the operator's toe, the operator's hip, the operator's trunk, the operator's neck, the operator's tongue, the operator's lip, the operator's eye and the operator's head.
213. The selection threshold controller of claim 208 wherein the means for changing of the  
10 selection threshold period includes means for decreasing the selection threshold period responsive to the move direction indicating with the body member a path toward the particular region.
214. The selection threshold controller of claim 208 wherein the means for changing of the  
15 selection threshold period includes means for increasing the selection threshold period responsive to the move direction indicating with the body member a path away from the particular region.
215. In a human interface system including  
20 a first surface on which may be displayed a plurality of regions each associated respectively with a menu option:  
wherein a body member of an operator may indicate successive locations on a second  
25 surface, each location corresponding to a location on the first surface; and  
wherein a particular one of the regions may be selected responsive to a period of intersection of two or more of the locations on the first surface and the particular region equalling or exceeding a selection threshold period;  
a selection threshold controller comprising a threshold controller for changing the selection  
30 threshold period responsive to one of:  
(1) a path indicated by two or more of the successive locations on the first surface; and  
(2) one of the locations on the first surface intersecting a predetermined region on the first surface.

216. An apparatus for selecting an option from a menu, said apparatus for use with a general purpose computer system including a display on which may be displayed a cursor whose movement is responsive to a movement related signal, said apparatus comprising:
- (a) a medium readable by the general purpose computer system; and
  - (b) an access program, stored on the medium and executable by the general purpose computer system, for:
    - (1) at least partially delimiting a plurality of selectable regions with respect to the display, each of the plurality of selectable regions associated respectively with a menu option; and
    - (2) selecting the menu option associated with the particular one of the plurality of selectable regions most nearly along a path indicated by a cursor location on the display and the movement related signal in advance of an intersection of the cursor and said particular selectable region.
217. An apparatus for selecting an option from a menu, said apparatus for use with a general purpose computer system including a display on which may be displayed a cursor whose movement is responsive to a movement related signal, said apparatus comprising:
- (a) a medium readable by the general purpose computer system; and
  - (b) an access program, stored on the medium and executable by the general purpose computer system, for:
    - (1) at least partially delimiting a plurality of selectable regions with respect to the display, each of the plurality of selectable regions associated respectively with a menu option; and
    - (2) selecting the menu option associated with the particular one of the plurality of selectable regions most nearly along a path indicated by a cursor location on the display and the movement related signal in response to an intersection of the cursor and said particular selectable region.
218. An apparatus for selecting an option from a menu, said apparatus for use with a general purpose computer system including a display on which may be displayed a cursor whose movement is responsive to a movement related signal, said apparatus comprising:
- (a) a medium readable by the general purpose computer system; and
  - (b) an access program, stored on the medium and executable by the general purpose computer system, for:

- 5
- (1) at least partially delimiting a plurality of selectable regions with respect to the display, each of the plurality of selectable regions associated respectively with a menu option; and
  - (2) changing a selection threshold period responsive to a cursor path;
  - (3) detecting an intersection of the cursor and any of the plurality of selectable regions; and
  - (4) in response to the period of the intersection equalling or exceeding the selection threshold period, selecting the menu option associated with the intersected selectable region.

10

219. An apparatus including a surface, for measuring an individual's ability to move a position indicator on the surface in a direct path from a starting location on the surface to an ending location on the surface, said position indicator indicative of a position of one of the individual's body members, said apparatus comprising:

15

- (a) the surface;
- (b) position indicating with the body member means for indicating with the body member on the surface a position of the body member;
- (c) collection means for collecting data indicative of a succession of the indicated positions on the surface; and
- (d) measurement means for measuring the deviation of the path indicated by the collected data from a predetermined path between the starting location and the ending location.

20

220. An interactive terminal, including a display on which may be displayed:

25

a plurality of selectable regions, each of the plurality of selectable regions associated respectively with a menu option and a selection threshold period; and  
a cursor whose movement is responsive to the movement of a body member of an operator;

said terminal comprising:

30

- (a) means for displaying the plurality of selectable regions on the display; and
- (b) control means for:
  - (1) in response to cursor movement toward a particular one of the plurality of selectable regions, decreasing the selection threshold period associated with the particular selectable region;
  - (2) in response to cursor movement diverging from a path toward the particular

selectable region, increasing the selection threshold period associated with the particular selectable region;

- (3) detecting an intersection of the cursor and any of the plurality of selectable regions; and
- (4) in response to the period of the intersection being equal to or greater than the selection threshold period associated with the intersected selectable region, selecting the menu option associated with the intersected selectable region.

221. The terminal of claim 220 wherein the plurality of selectable regions together at least partially circumscribes an area on the display.

222. A data entry system comprising:

(a) a computer system including:

- (1) a display on which a moveable cursor may be displayed and then moved responsive to a movement related signal and on which a plurality of selectable regions may be displayed, each selectable region associated respectively with a sequence of one or more characters and a character sequence signal representing the associated sequence of one or more characters; and
- (2) a processing unit coupled to the display and capable of executing an application program operative to accept any of the character sequence signals; and

(b) an input program, for execution on the processing unit, for inputting to the application program the character sequence signal representing the sequence of one or more characters associated with the particular one of the plurality of selectable regions most nearly along the path indicated by a cursor location and the movement related signal in advance of an intersection of the cursor and said particular selectable region.

223. A data entry system comprising:

(a) a computer system including:

- (1) a display on which a moveable cursor may be displayed and then moved responsive to a movement related signal and on which a plurality of selectable regions may be displayed, each selectable region associated respectively with a sequence of one or more characters; and
- (2) a processing unit coupled to the display and capable of executing an application program operative to accept any of the plurality of sequences of one or more

characters; and

- (b) an input program, for execution on the processing unit, for inputting to the application program the sequence of one or more characters associated with the particular one of the plurality of selectable regions most nearly along a cursor path, said input to the application program being responsive to an intersection of the cursor and said particular selectable region.

5

10

224. The data entry system of claim 220 wherein the input program further comprises means for changing a selection threshold period associated with said particular selectable region and wherein said input to the application program is further responsive to the duration of the period of the intersection equalling or exceeding the selection threshold period.

15

225. In a computer system including a display on which may be displayed a moveable cursor, and on which may be displayed a menu having a plurality of menu options, each of the menu options associated respectively with a selectable region on the display, an apparatus for selecting any one of the plurality of menu options, said apparatus comprising:

- (a) identification means for identifying which one of the plurality of selectable regions is most nearly along a cursor path; and  
(b) selection means for selecting the menu option associated with the identified selectable region in advance of an intersection of the cursor and the identified selectable region.

20

25

226. In a computer system including a display on which may be displayed a moveable cursor, and on which may be displayed a menu having a plurality of menu options, each of the menu options associated respectively with a selectable region on the display, an apparatus for selecting any one of the plurality of menu options, said apparatus comprising:

- (a) means for detecting an intersection of the cursor and any one of the selectable regions;  
and  
(b) selection means, responsive to the detected intersection, for selecting the menu option associated with the particular selectable region most nearly along a cursor path.

30

227. The apparatus of claim 226 wherein the selection means further comprises means for decreasing a selection threshold period associated with the particular selectable region and wherein the selection means is further responsive to the duration of the period of the intersection equalling or exceeding the selection threshold period.

228. A speech synthesis system comprising:

- (a) a display on which may be displayed a plurality of selectable regions, each of the selectable regions associated respectively with a sequence of one or more characters;
- 5 (b) a speech synthesizer; and
- (c) control means for:
  - (1) receiving a movement related signal and moving a cursor on the display responsive to the movement related signal;
  - (2) repetitively
    - 10 (A) detecting an intersection of the cursor and any of the plurality of selectable regions;
    - (B) changing a selection threshold period responsive to a cursor path to the intersected selectable region; and
    - (C) in response to the period of the intersection equalling or exceeding the selection threshold period, appending the sequence associated with the intersected selectable region to at least one previously selected sequence;
  - 15 and
  - (3) speaking, by means of the speech synthesizer, the word spelled by the appended sequences.

20

229. A device controller comprising:

- (a) means for displaying a plurality of selectable regions on a surface, each of the plurality of selectable regions associated respectively with a device control function;
- (b) movement related signal receiving means for receiving a movement related signal;
- 25 (c) signal generating means coupled to a device for generating a device control signal; and
- (d) control means for:
  - (1) moving a cursor on the surface in response to the received movement related signal;
  - (2) changing a selection threshold period responsive to a cursor path; and
  - 30 (3) detecting an intersection of the cursor and any one of the selectable regions;
  - (4) in response to the period of the intersection equalling or exceeding the selection threshold period, generating a device control signal corresponding to the device control function associated with the intersected selectable region.

230. The controller of claim 229 wherein the device includes a wheelchair.

231. In a computer system, an apparatus for measuring an individual's ability to move one of the individual's body members directly from a starting position to an ending position, said apparatus comprising:

- (a) receiving means, coupled to the computer system, for receiving a sampling among data indicative of successive positions of the body member; and
- (b) measurement means, executable on the computer system, for measuring deviation of the path indicated by the received position data from a direct path between the starting position and the ending position.

232. The apparatus of claim 231 further comprising:

- (c) a display, coupled to the computer system, on which a moveable cursor may be displayed; and
- (d) cursor movement means for moving the cursor on the display responsive to the received position data.

233. An apparatus for selecting an option from a menu, said apparatus comprising:

- (a) means for displaying a plurality of selectable regions on a surface, each of the plurality of selectable regions associated respectively with a menu option and a selection threshold period; and
- (b) movement related signal receiving means for receiving a movement related signal; and
- (c) control means for:
  - (1) moving a cursor on the surface in response to the received movement related signal;
  - (2) in response to a cursor path not toward any one of the plurality of selectable regions, increasing the selection threshold period associated with said one of the plurality of selectable regions;
  - (3) detecting an intersection of the cursor and any one of the plurality of selectable regions; and
  - (4) in response to the period of the intersection being equal to or greater than the selection threshold period associated with the intersected selectable region, selecting the menu option associated with the intersected selectable region.

234. A method of selecting an option from a menu, said method comprising the steps of:

displaying a plurality of selectable regions on a surface, each of the plurality of  
selectable regions associated respectively with a menu option;

5

detecting a movement related signal and in response moving a cursor on the surface;

in response to an intersection of the cursor and the selectable region most nearly along  
a cursor path, selecting the menu option associated with the intersected selectable  
region.

10

235. The method of claim 234 further comprising the step of changing a selection threshold period  
associated with the selectable region most nearly along the cursor path and wherein the  
selecting step is further responsive to the duration of the period of the intersection equalling  
or exceeding the selection threshold period.

15

236. A method of selecting an option from a plurality of options, each of the plurality of options  
shown adjacent an edge of a display, said method comprising the steps of:

20

detecting a movement related signal and in response moving a cursor on the display;

selecting the option shown most nearly along a cursor path in advance of an  
intersection of the cursor and the selected option;

25

237. A method of measuring an individual's ability to move one of the individual's body members  
in a direct path from a starting position to an ending position, said method comprising the  
steps of:

collecting a sampling among data indicative of successive positions of the body  
member; and

30

measuring the deviation of the path indicated by the collected data from a direct path  
between the starting position and the ending position.

238. An apparatus for selecting an option from a menu, said apparatus comprising:

- (a) cursor movement means for receiving a movement related signal and for moving a cursor on a display responsive to the received movement signal;
- (b) delimit means for delimiting with respect to the display a first plurality of regions and a second plurality of selectable regions, each of the first plurality of regions associated respectively with one of the second plurality of selectable regions, each of the second plurality of selectable regions associated respectively with a menu option, wherein at least one of the first plurality of regions is not coterminous with its associated one of the second plurality of selectable regions; and
- (c) selection means, responsive to an intersection of the cursor and any one of the first plurality of regions and to a selection event associated with the one of the second plurality of selectable region associated with the intersected one of the first plurality of regions, for selecting the menu option associated with the selectable region associated with the selection event.

239. The apparatus of claim 238 wherein the delimit means includes means for displaying at least part of at least one of the first plurality of regions on the display.

240. The apparatus of claim 238 wherein the delimit means includes means for displaying at least part of at least one of the second plurality of selectable regions on the display.

241. The apparatus of claim 238 wherein each of the at least one of the first plurality of regions intersects its associated one of the second plurality of selectable regions.

242. The apparatus of claim 241 wherein each of the at least one of the first plurality of regions shares at least one side with its associated selectable region.

243. The apparatus of claim 238 wherein none of the first plurality of regions is coterminous with its associated selectable region.

244. The apparatus of claim 238 wherein the first plurality of regions together at least partially circumscribes a first region on the display.

245. The apparatus of claim 244 wherein the second plurality of selectable regions together at

least partially circumscribes a second region on the display.

246. The apparatus of claim 238 wherein the selection event includes the durations of one or more successive periods of intersection of the cursor and the selectable region associated with the selection event equalling or exceeding a selection threshold period.
247. The apparatus of claim 238 wherein the selection means includes means for receiving a switch operation signal; and wherein the first selection event includes:
- (1) an intersection of the cursor and the selectable region associated with the selection event; and
  - (2) at or near the time the intersection occurs, receipt of the switch operation signal.
248. The apparatus of claim 238 wherein the intersected one of the first plurality of regions is adjacent another one of the first plurality of regions and the intersection is the earliest intersection of a plurality of intersections of the cursor and the union of the intersected one of the first plurality of regions and the adjacent one of the first plurality of regions.
249. An apparatus for selecting an option from a menu, said apparatus for use with a general purpose computer system including a display on which may be displayed a cursor whose movement is responsive to a movement related signal, said apparatus comprising:
- (a) a medium readable by the general purpose computer system; and
  - (b) an access program, stored on the medium and executable by the general purpose computer system, for:
    - (1) delimiting a first plurality of regions and a second plurality of selectable regions with respect the display, each of the first plurality of regions associated respectively with one of the second plurality of selectable regions, each of the second plurality of selectable regions associated respectively with a menu option, the second plurality of selectable regions together at least partially circumscribing a third region on the display; wherein at least one of the first plurality of regions is not coterminous with its associated one of the second plurality of selectable regions; and
    - (2) responsive to an intersection of the cursor and any one of the first plurality of regions and to a selection event associated with the one of the second plurality of selectable region associated with the intersected one of the first plurality of

regions, selecting the menu option associated with the selectable region associated with the selection event.

250. For use with a computer system including a display, the computer system being capable of  
5 executing an application program, a computer access device for an operator having impaired motor control, said device comprising:

- (a) cursor movement means for receiving a movement related signal and for moving the cursor on the display responsive to the received movement signal;
- (b) display means for displaying a first plurality of regions on the display, each of the first  
10 plurality of regions associated respectively with one of a second plurality of selectable regions, each of the first plurality of regions including all the area of its associated one of the second plurality of selectable regions, the first plurality of regions together at least partially circumscribing a third region on the display on which may be displayed at least part of the output of the application program, the second plurality of selectable  
15 regions together at least partially circumscribing the third region, each of the second plurality of selectable regions associated respectively with a menu option, at least one of the menu options representing an input for the application program; and wherein the display means, responsive to an intersection of the cursor and any one of the first plurality of regions, is operative to display on the display at least part of the one of the  
20 second plurality of selectable regions associated with the intersected region; and
- (c) input means, responsive to a dwell event associated with any one of the second plurality of selectable regions associated with one of the at least one menu options representing an input for the application program, for inputting to the application program the menu option associated with the selectable region associated with the  
25 dwell event.

251. In a human interface system wherein a body member of an operator may indicate successive locations on a surface, a menu option selector for selecting a menu option from a plurality of menu options, said menu option selector comprising:

- (a) the surface on which may be delimited a first plurality of regions and a second  
30 plurality of selectable regions, each of the first plurality of regions associated respectively with one of the second plurality of selectable regions, each of the second plurality of selectable regions associated respectively with a menu option; and wherein at least one of the first plurality of regions is not coterminous with its associated one of

regions, selecting the menu option associated with the selectable region associated with the selection event.

250. For use with a computer system including a display, the computer system being capable of  
5 executing an application program, a computer access device for an operator having impaired motor control, said device comprising:

- (a) cursor movement means for receiving a movement related signal and for moving the cursor on the display responsive to the received movement signal;
- (b) display means for displaying a first plurality of regions on the display, each of the first  
10 plurality of regions associated respectively with one of a second plurality of selectable regions, each of the first plurality of regions including all the area of its associated one of the second plurality of selectable regions, the first plurality of regions together at least partially circumscribing a third region on the display on which may be displayed at least part of the output of the application program, the second plurality of selectable  
15 regions together at least partially circumscribing the third region, each of the second plurality of selectable regions associated respectively with a menu option, at least one of the menu options representing an input for the application program; and wherein the display means, responsive to an intersection of the cursor and any one of the first plurality of regions, is operative to display on the display at least part of the one of the  
20 second plurality of selectable regions associated with the intersected region; and
- (c) input means, responsive to a dwell event associated with any one of the second plurality of selectable regions associated with one of the at least one menu options representing an input for the application program, for inputting to the application program the menu option associated with the selectable region associated with the  
25 dwell event.

251. In a human interface system wherein a body member of an operator may indicate successive locations on a surface, a menu option selector for selecting a menu option from a plurality of menu options, said menu option selector comprising:

- (a) the surface on which may be delimited a first plurality of regions and a second  
30 plurality of selectable regions, each of the first plurality of regions associated respectively with one of the second plurality of selectable regions, each of the second plurality of selectable regions associated respectively with a menu option; and wherein at least one of the first plurality of regions is not coterminous with its associated one of

the second plurality of selectable regions; and

(b) in response to:

- (1) an intersection of one of the successive locations and any one of the first plurality of regions; and
- (2) thereafter, the durations of one or more successive periods of intersection of two or more of the successive locations and the one of the second plurality of selectable regions associated with the intersected one of the first plurality of regions,

a selector for selecting the menu option associated with the one of the second plurality of selectable regions associated with the intersected one of the first plurality of regions.

252. A speech synthesis system comprising:

(a) a computer system including a display on which may be displayed a first plurality of regions, each of the first plurality of regions associated respectively with one of a second plurality of selectable regions, each of the second plurality of selectable regions associated respectively with a sequence of one or more characters;

(b) a speech synthesizer coupled to the computer system; and

(c) control means for:

- (1) receiving a movement related signal and moving a cursor on the display responsive to the movement related signal;
- (2) repetitively, responsive to:
  - (A) an intersection the cursor any one of the first plurality of regions; and
  - (B) thereafter, the durations of one or more periods of intersection of the cursor and the one of the second plurality of selectable regions associated with the intersected one of the first plurality of regions.

appending to at least one previously selected sequence the sequence associated with the one of the second plurality of selectable regions associated with the intersected one of the first plurality of regions; and

- (3) speaking, by means of the speech synthesizer, the word spelled by the appended sequences.

253. A method of selecting an option from a menu, said method comprising the steps of:

receiving a movement related signal and moving a cursor on a surface responsive thereto;

delimiting a first plurality of regions and a second plurality of selectable regions with respect to a surface, each of the first plurality of regions associated respectively with one of the second plurality of selectable regions, each of the second plurality of selectable regions associated respectively with a menu option; wherein at least one of the first plurality of regions is not coterminous with its associated one of the second plurality of selectable regions; and

responsive to an intersection of the cursor and any one of the first plurality of regions and to a selection event associated with the one of the second plurality of selectable region associated with the intersected one of the first plurality of regions, selecting the menu option associated with the selectable region associated with the selection event.

254. An apparatus, including a surface on which may be displayed a moveable cursor, said apparatus allowing an operator to align a pointer with a predetermined location on the surface, said apparatus comprising:

- (a) display means for displaying the cursor on the surface;
- (b) movement related signal receiving means for receiving a movement related signal; and
- (c) control means for moving the cursor in response to the movement related signal and for thereafter inhibiting movement of the cursor for a first period of time in response to an operator action detected by the movement related signal receiving means.

255. The apparatus of claim 254 wherein the surface includes a display area and the display means further includes means for confining at least part of the cursor to the display area.

256. The apparatus of claim 254 wherein the operator action includes one of:

- (1) an intersection of at least part of the cursor and a region on the surface for a second period of time; and
- (2) a switch operation.

257. The apparatus of claim 254 further comprising start indication means for indicating the start of the first period of time and end indication means for indicating the end of the first period of time.

258. The apparatus of claim 257 wherein the start indication means includes changing means for

changing the appearance of the cursor and the end indication means includes restoring means for restoring the appearance of the cursor to the appearance it had before the changing means changed it.

- 5      259. The apparatus of claim 254 wherein the movement related signal is responsive to the movement of a body member of an operator having impaired ability to sense the position of the body member and the apparatus further comprises tactile indication means for indicating tactilely to the operator the position of the body member.
- 10      260. An apparatus, including a surface on which may be displayed a moveable cursor, said apparatus allowing an operator to align a pointer producing a movement related signal with the cursor, said apparatus comprising:
- (a) display means for displaying the cursor on the surface;
  - (b) movement related signal receiving means for receiving the movement related signal;
  - 15      (c) detection means for detecting a switch operation; and
  - (d) control means for moving the cursor responsive to the movement related signal and for thereafter inhibiting movement of the cursor for a first period of time in response to a switch operation detected by the detection means.
- 20      261. An apparatus, including a surface on which may be displayed a moveable cursor, said apparatus allowing an operator to align a pointer with a predetermined location on the surface, said apparatus comprising:
- (a) display means for displaying the cursor on the surface;
  - (b) movement related signal receiving means for receiving a movement related signal;
  - 25      (c) switch operation signal receiving means for detecting a switch operation signal; and
  - (d) control means for
    - (1) moving the cursor responsive to the movement related signal;
    - (2) thereafter, in response to a detected first switch operation, inhibiting movement of the cursor; and
    - 30      (3) thereafter, in response to a detected second switch operation, moving the cursor responsive to the movement related signal.

262. In a human interface system including a surface on which may be displayed a cursor whose movement usually tracks the movement of a body member of an operator, an apparatus for

aligning the body member of the operator with a predetermined location on the surface, said apparatus comprising a cursor controller for:

- (a) detecting movement of the body member of the operator;
- (b) detecting an operator action; and
- 5 (c) moving the cursor on the surface in response to the movement of the body member of the operator and thereafter inhibiting movement of the cursor for a first period of time in response to the detected operator action.

10 263. The apparatus of claim 262 wherein the cursor controller is further operative to display a target at the predetermined location on the surface during at least part of the first period of time and to display the cursor at the predetermined location at the end of the first period of time.

15 264. The apparatus of claim 262 wherein the cursor controller is further operative to display a target in or in close proximity to the location of the cursor immediately prior to the start of the first period of time.

20 265 The apparatus of claim 262 wherein the operator action includes one of:

- (1) the intersection of the cursor and a region on the display area for a second period of time; and
- (2) a switch operation.

25 266. In an interactive terminal including:

- (1) a display on which a moveable first cursor may be displayed; and
- (2) a region on the display, said region not greater in size than the display,

wherein movement of the hotspot of the first cursor within the region reflects the movement of at least one body member of the operator of the interactive terminal and wherein movement of a body member that would, if accurately reflected in cursor movement, take the cursor out of the region, is not reflected in cursor movement, such that the hotspot of the

30 cursor remains on the display, said interactive terminal comprising a cursor controller for:

- (a) inhibiting display of the first cursor;
- (b) displaying a stationary target on the display for a prescribed period of time; and then
- (c) displaying a moveable stationary target in or in close proximity to the position of the stationary target.

so that the operator may align the body member with the position of the stationary target.

267. For use with a computer system including a display upon which a moveable cursor may be displayed, an apparatus for temporarily inhibiting cursor movement, said apparatus

5 comprising:

- (a) a pointer; and
- (b) a program executable by the computer system for moving the cursor responsive to the pointer and for thereafter inhibiting cursor movement for a prescribed period of time in response to an operator action.

10

268. An apparatus comprising:

- (a) a computer system including a display on which a moveable cursor may be displayed;
- (b) movement related signal receiving means, coupled to the computer system, for receiving a movement related signal; and
- 15 (c) program means, coupled to the computer system, for moving the cursor responsive to the movement related signal and for thereafter temporarily inhibiting cursor movement in response to a signal detected by the movement related signal receiving means.

269. An apparatus allowing an operator having impaired motor control to align a pointer with a cursor, said apparatus comprising:

20

- (a) a display area;
- (b) movement related signal receiving means for receiving a movement related signal;
- (c) operator action detection means for detecting an operator action; and
- (d) control means for:
  - 25 (1) displaying a first cursor on the display area;
  - (2) moving the first cursor responsive to the movement related signal while confining the hotspot of the first cursor to the display area; then
  - (3) in response to the detected operator action, displaying a second cursor differing in configuration from the first cursor at a predetermined location on the display area during a first period of time; and
  - 30 (4) at the end of the first period of time, displaying the first cursor in or in close proximity to the predetermined location on the display area.

270. The apparatus of claim 269 further comprising means for displaying a plurality of regions on

the display area and wherein the predetermined location is a location associated with the region intersected by the hotspot of the first cursor when the operator action detection means detects the operator action.

5     271. An apparatus allowing an operator having below normal motor capabilities to bring a pointer and a cursor coupled to the pointer into alignment with each other, said apparatus comprising:

(a) a display area;

(b) a processor operative to:

10         (1) display a first cursor on the display area,

(2) move the first cursor responsive to operator movement while confining at least part of the first cursor to the display area; and then

(3) responsive to an intersection of the first cursor and a region on the display area for a first period of time:

15         (i) remove the first cursor from the display area for a second period of time; and

(ii) during the second period of time, display at a predetermined location on the display area a second cursor differing in configuration from the first cursor.

20

272. For use with a system comprising a pointer and a surface on which is displayed a first cursor whose movement on the surface is responsive to the movement of the pointer, a method of aligning the first cursor with a predetermined location on the surface, said method comprising the steps of:

25     (a) producing the first cursor on the surface;

(b) moving the first cursor responsive to the movement of the pointer, said movement restricted to a region on the surface; and then

(c) responsive to an operator action, producing a second cursor at a predetermined location on the surface for a period of time; and

30     (d) positioning the first cursor in or in close proximity to the predetermined location..

273. The method of claim 272 further comprising the steps of:

indicating with the body member the start of the period of time; and

indicating with the body member the end of the period of time.

274. The method of claim 273 wherein the step of indicating with the body member the start of the period of time includes generating a first signal and the step of indicating with the body member the end of the period of time includes generating a second signal distinct from the first signal.
275. In a menu interface system, an apparatus for ordering menu options comprising:
- (a) order means for ordering a plurality of named menu options in an order responsive to the length of the name of each named menu option; and
  - (b) display means for displaying the plurality of named menu options in said order.
276. The apparatus of claim 275 wherein the displayed plurality of named menu options together at least partially circumscribe a region on a display.
277. The apparatus of claim 275 wherein each of the displayed menu options is adjacent at least one other display menu option.
278. The apparatus of claim 275 wherein the order means includes an arithmetic logic unit.
279. The apparatus of claim 275 wherein the name of each named menu option includes letters and the length of each name includes the number of letters in the name.
280. The apparatus of claim 275 wherein the name of each named menu option includes letters and the order means is further responsive to the alphabetic order of each name.
281. In a menu interface system, an apparatus for displaying words, said apparatus comprising:
- (a) order means for ordering a plurality of words in an order responsive to the number of letters in each word; and
  - (b) display means for displaying the plurality of words in said order;
- whereby an operator who knows the relative number of letters in a desired word and one of the plurality of words may limit his search for the desired word.
282. The apparatus of claim 281 wherein the display means includes a display.

283. An apparatus for selecting a sequence of one or more words, said apparatus comprising:

- (a) display means for displaying on a display a plurality of sequences of one or more words in an order responsive to the length of each sequence;
- (b) cursor movement means for receiving a movement related signal and for moving a cursor on the display responsive to the received movement signal; and
- (c) selection means, responsive to a selection event associated with any one of the sequences, for selecting the sequence associated with the selection event.

284. The apparatus of claim 283 wherein each sequence is composed of one word.

285. The apparatus of claim 283 wherein each sequence includes one or more characters and the length of each sequence includes the number of characters in the sequence.

286. The apparatus of claim 283 wherein the selection event includes an intersection of the cursor and a region on the display associated with the word associated with the selection event.

287. The apparatus of claim 283 wherein at least one of the sequence represents a sentence.

288. The apparatus of claim 283 further comprising means for modifying the selected sequence.

289. A speech synthesis system comprising:

- (a) a display for displaying a plurality of named menu options in an order responsive to the length of the name of each named menu option, each of the named menu options associated respectively with a sequence of one or more characters;
- (b) a speech synthesizer; and
- (c) control means for:
  - (1) selecting, responsive to a selection event associated with any one of the named menu options, the sequence of one or more characters associated with the named menu option associated with the selection event; and
  - (2) speaking, by means of the speech synthesizer, the selected sequence of one or more characters.

290. For use with a computer capable of executing an application program, a method of data entry comprising the steps of:

- (a) displaying a plurality of named menu options in an order responsive to the length of the name of each named menu option, each of the named menu options associated respectively with a sequence of one or more characters; and
- (b) inputting to the application program, responsive to a selection event associated with one of the named menu options, the sequence of one or more characters associated with the named menu option associated with the selection event.

291. The method of claim 290 wherein the name of at least one of the named menu options represents the sequence of one or more characters associated with the at least one name menu option.

292. In a menu interface including:

- (1) a menu including a plurality of menu options; and
- (2) a display area with respect to which may be at least partially delimited a plurality of selectable regions, each selectable region associated respectively with one of the plurality of menu options;

an apparatus for selecting one of the menu options, said apparatus comprising:

- (a) delimit means for at least partially delimiting the selectable regions;
- (b) indication means, coupled to the delimit means, for displaying each menu option on the display area, wherein the location of each displayed menu option indicates the location of the associated selectable region and wherein none of the displayed menu options intersects the selectable region associated therewith; and
- (c) selection means, responsive to a selection event associated with any one of the selectable regions, for selecting the menu option associated with the selectable region associated with the selection event.

293. The apparatus of claim 292 wherein none of the displayed menu options is located adjacent the selectable region associated therewith.

294. The apparatus of claim 293 wherein the relative location of each displayed menu option with respect to the other displayed menu options indicates the relative location of the associated selectable region with respect to the other selectable regions.

295. The apparatus of claim 292 wherein each selectable region is located outside the display

area.

296. The apparatus of claim 295 wherein each selectable region is unbounded on at least one side.

5 297. The apparatus of claim 292 wherein each selectable region is located on the display area adjacent an edge of the display area.

298. The apparatus of claim 292 wherein the plurality of selectable regions together at least partially circumscribe a region on the display area.

10

299. The apparatus of claim 292 wherein the plurality of selectable regions together at least partially circumscribe a transparent region within the display area.

15

300. The apparatus of claim 292 wherein each of the menu options represents a sequence of one or more graphic symbols, one or more sequences of the plurality of sequences including one or more ideographs, each of the plurality of sequences having a common characteristic.

301. The apparatus of claim 292 wherein each of the menu options represents a symbol in a symbol set.

20

302 The apparatus of claim 301 wherein the symbol set is any one of the Picture Communication Symbols symbol set, Rebus symbol set, Picsyms symbol set, Pictogram Ideogram Communication Symbols symbol set, Yerkish symbol set, Blissymbolics symbol set, and a set of depictions of the signs of a manual sign language.

25

303. The apparatus of claim 292 wherein each of the menu options represents a word, each word beginning with a common sequence of one or more characters.

30

304. The apparatus of claim 303 wherein the common sequence of one or more characters includes a letter from one of the Afrikaans, Albanian, Amharic, Arabic, Armenian, Assamese, Assyrian, Avar, Azerbaijani, Balinese, Bamara, Bantu, Bashkir, Basque, Bengali, Birhari, Bulgarian, Buluba-Lulua, Burmese, Buryat, Byelorussian, Caddoan, Catalan, Chechen, Chikaranga, Chippewa, Choctaw, Church Slavik, Chuvash, Coptic, Cree, Croatian, Cyrillic, Czech, Dakota, Danish, Dari, Devanagari, Dutch, Dzongkha, English, Eskimo,

Esperanto, Estonian, Ewe, Farsi, Fijian, Filipino, Finnish, Flemish, French, Fulani, Gaelic, Galician, Georgian, German, Greek, Gujarati, Gurmakhi, Harari, Hausa, Hawaiian, Hebrew, Hindi, Hiragana, Ibo, Icelandic, Indonesian, Irish, Iroquoian, Italian, Kabardian, Kalmyk, Kannada, Kanuri, Kashmiri, Katakana, Kazakh, Khasi, Khmer, Kirghiz, Kishmiri, Komi, Kongo, Kurdish, Lao, Latin, Latvian, Lithuanian, Lu-Guanda, Macedonian, Magahi, Maithili, Makua, Malagasy, Malay, Malayalam, Maltese, Mandingo, Manipuri, Marathi, Masai, Mizo, Moldavian, Mongolian, Munda, Naga, Navaho, Nyanja, Nepalese, Norwegian, Oriya, Oromo, Ossetian, Pashto, Polish, Portugese, Punjabi, Rajasthani, Rhaeto-Romanic, Rumanian, Russian, Samoan, Sangs, Serbian, Serbo-Croatian, Sinhalese, Sinhi, Sioux, Slovak, Slovenia, Spanish, Sundanese, Swahili, Swedish, Syriac, Tadjik, Tagalog, Tajik, Tamil, Tatar, Telugu, Thai, Tibetan, Turkish, Turkmen, Udmurt, Uighur, Ukranian, Umbundu, Urdu, Uzbek, Vietnamese, Visayan, Welsh, Yakut, Yoruba and phonetic alphabets.

- 15 305. The apparatus of claim 292 wherein each of the menu options represents a sequence including one or more characters, each sequence including a common sequence of one or more characters.
- 20 306. The apparatus of claim 292 wherein the indication means further comprises display means for displaying a plurality of indicating regions, each indicating region associated respectively with one of the menu options, each indicating region displayed in a location intersecting or near the associated displayed menu option, and wherein no one indicating region intersects the selectable region associated with the menu option associated with said one indicating region.
- 25 307. The apparatus of claim 306 wherein at least part of each indicating region is displayed in one manner and at least part of the selectable region associated with the menu option associated with each indicating region is displayed in a manner similar to the one manner.
- 30 308. The apparatus of claim 307 wherein the manner of display is any one of:
- (1) a size;
  - (2) a shape;
  - (3) a hue;
  - (4) a brightness;

- (5) a contrast;
- (6) a tone;
- (7) a dithering;
- (8) a fill;
- (9) a font;
- (10) a blinking;
- (11) a hatching; and
- (12) a pattern.

10 309. The apparatus of claim 306 further comprising movement related signal receiving means for receiving a movement related signal indicating a location with respect to the display area; and wherein the indication means further comprises intersection indication means for indicating an intersection of the location and any one of the selectable regions in the indicating region associated with the menu option associated with the intersected selectable region.

15 310. The apparatus of claim 306 further comprising movement related signal receiving means for receiving a movement related signal indicating successive locations with respect to the display area; and wherein the indication means further comprises intersection indication means for indicating the duration of a period of intersection of at least two of the successive locations and any one of the selectable regions in the indicating region associated with the menu option associated with the intersected selectable region.

20 311. The apparatus of claim 306 wherein the selection means further comprises selection indication means, responsive to the selection event, for indicating that the selection event has occurred.

25 312. The apparatus of claim 292 wherein the selection means includes a processor coupled to a switch and the selection event includes an operation of the switch.

30 313. The apparatus of claim 292 wherein the selection means includes timing circuitry and the selection event includes a signal from the timing circuitry indicating an expiration of a predetermined period of time.

314. A menu option selector comprising:

- (a) a first menu including a first plurality of menu options;
- (b) a surface including a display area with respect to which may be at least partially delimited a plurality of selectable regions, each selectable region capable of being associated respectively with one of the first plurality of menu options;
- (c) a first plurality of indicators on the display area, each of the first plurality of indicators associated respectively with one of the first plurality of menu options, and each one of the first plurality of indicators indicating the location of the selectable region capable of being associated with the menu option associated with said one of the first plurality of indicators; and
- (d) means for selecting any one of the selectable regions.

315. The menu option selector of claim 314 wherein each of the selectable regions is outside the display area.

316. The menu option selector of claim 315 further comprising a second menu including a second plurality of menu options, each of the second plurality of menu options capable of being associated respectively with one of the selectable regions; and a second plurality of indicators on the display area, each of the second plurality of indicators associated respectively with one of the second plurality of menu options, and each one of the second plurality of indicators indicating the location of the selectable region capable of being associated with the menu option associated with said one of the second plurality of indicators.

317. The menu option selector of claim 316 further comprising association means for associating the plurality of selectable regions with either one of the first plurality of menu options or the second plurality of menu options.

318. The menu option selector of claim 317 wherein the association means is responsive to a selection event.

319. The menu option selector of claim 317 wherein the association means is responsive to an expiration of a predetermined period of time.

320. For use with a general purpose computer system including a display with respect to which may be at least partially delimited a plurality of selectable regions, each selectable region associated respectively with a menu option, an apparatus for selecting a menu option from the plurality of menu options, said apparatus comprising:

- 5 (a) a medium readable by the general purpose computer system; and
- (b) a program, stored on the medium and executable by the general purpose computer system, for:
  - (1) at least partially delimiting the selectable regions with respect to the display;
  - 10 (2) displaying each menu option on the display, the location of each displayed menu option indicating the location of the associated selectable region and none of the displayed menu options intersecting the selectable region associated therewith; and
  - (3) responsive to a selection event associated with any one of the selectable regions, selecting the menu option associated with the selectable region associated with
  - 15 the selection event.

321. In a computer system including a display with respect to which may be at least partially delimited a plurality of selectable regions, each selectable region associated respectively with a menu option, an apparatus for selecting a menu option from the plurality of menu options, said apparatus comprising:

- 20 (a) the computer system; and
- (b) a program, for execution on the computer system, for:
  - (1) displaying a plurality of indicating regions on the display, each indicating region associated respectively with one of the menu options:
  - 25 (2) displaying each menu option in a location intersecting or near the associated indicating region, wherein each indicating region:
    - (i) indicates the location of the selectable region associated with the menu option associated with the indicating region; and
    - (ii) does not intersect the selectable region associated with the menu option
    - 30 associated with the indicating region; and
  - (3) selecting, responsive to a selection event associated with any one of the selectable regions, the menu option associated with the selectable region associated with the selection event.

322. A speech synthesis system comprising:

- (a) a display;
- (b) a speech synthesizer; and
- (c) control means for:
  - (1) receiving a movement related signal indicating successive locations on the display;
  - (2) displaying:
    - (i) a plurality of selectable regions on the display, the plurality of selectable regions together at least partially circumscribing a region on the display, each selectable region associated respectively with a sequence of one or more characters; and
    - (ii) the plurality of sequences in the at least partially circumscribed region, wherein the location of each sequence indicates the location of the associated selectable region;
  - (2) repetitively, in response to an intersection of one of the successive locations and a selectable region and a dwell event, appending the sequence associated with the intersected selectable region to at least one previously selected sequence; and
  - (3) speaking, by means of the speech synthesizer, the word spelled by the appended sequences.

323. For use with a menu interface including a display area and a menu hierarchy including a menu including a plurality of menu options, at least one of the menu options associated with a submenu including a plurality of submenu options, a method of selecting a submenu option from the menu hierarchy, said method comprising the steps of:

at least partially delimited a plurality of selectable regions with respect to the display area, each selectable region associated respectively with one of the menu options and with one of the submenu options;

displaying a plurality of submenu indicating regions on the display area, each submenu indicating region associated respectively with one of the submenu options, wherein each submenu indicating region is displayed in a manner indicating the location of the selectable region associated with the submenu option associated with the submenu indicating region;

selecting, responsive to a first selection event associated with any one of the selectable regions, the menu option associated with the selectable region associated with the first selection event; and

5       thereafter selecting, responsive to a second selection event associated with any one of the selectable regions, the submenu option associated with the selectable region associated with the second selection event.

10       324. The method of claim 323 further comprising the step of displaying a plurality of menu indicating regions, each menu indicating region associated respectively with one of the menu options, wherein each menu indicating region is displayed in a manner indicating the location of the selectable region associated with the menu option associated with the menu indicating region.

15       325. The method of claim 324 further comprising the step of displaying a plurality of submenu indicating regions, each submenu indicating region associated respectively with one of the submenu options, wherein each submenu indicating region is displayed in a manner indicating the location of the selectable region associated with the submenu option associated with the submenu indicating region; and wherein the submenu indicating regions each  
20       intersect the menu indicating region associated with the menu option associated with the submenu.

The diagram illustrates a keyboard layout with the following keys and labels:

- 1302** points to the **Bksp** key.
- 1314** points to the **x** key.
- 1304** points to the **Edit** key.
- 1308** points to the **d** key.
- 1312** points to the **h** key.
- 1310** points to the **l** key.
- 1306** points to the **1** key.

The keyboard layout is organized into two main sections, separated by a vertical line. The top section contains the following keys (from left to right):

- Space
- a
- b
- c
- n
- o
- p
- Bksp

The bottom section contains the following keys (from left to right):

- 1
- 2
- 3
- +
- (
- )
- ↑
- Edit

The middle section contains the following keys (from left to right):

- d
- e
- f
- g
- q
- r
- s
- t

The bottom-most section contains the following keys (from left to right):

- 4
- 5
- 6
- 
- ←
- 
- ↓
- Words

The bottom-most section contains the following keys (from left to right):

- 7
- 8
- 9
- ÷
- '
- "
- :
- Alt

The bottom-most section contains the following keys (from left to right):

- Enter
- 0
- /
- =
- Esc
- Caps
- Shift
- Undo

# INTERNATIONAL SEARCH REPORT

Int:      nal Application No  
PCT/US 95/03591

## A. CLASSIFICATION OF SUBJECT MATTER

IPC 6    G06F3/00    G06F3/033    G06F3/023    G09B21/00    A61F4/00

According to International Patent Classification (IPC) or to both national classification and IPC

## B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)  
IPC 6    G06F    G09B    A61F

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practical, search terms used)

## C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category *	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
X	DE,U,93 00 231 (HASABI I.) 19 August 1993 see page 1, line 1 - page 6, line 2	34
A		43,44
X	--- PATENT ABSTRACTS OF JAPAN vol. 018 no. 460 (P-1793) ,26 August 1994 & JP,A,06 149534 (TOSHIBA CORP) 27 May 1994, see abstract	34

☒ Further documents are listed in the continuation of box C.

☒ Patent family members are listed in annex.

### \* Special categories of cited documents :

- \* "A" document defining the general state of the art which is not considered to be of particular relevance
- \* "E" earlier document but published on or after the international filing date
- \* "L" document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)
- \* "O" document referring to an oral disclosure, use, exhibition or other means
- \* "P" document published prior to the international filing date but later than the priority date claimed

\* "T" later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention

\* "X" document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone

\* "Y" document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art

\* "&" document member of the same patent family

# INTERNATIONAL SEARCH REPORT

International application No.

PCT/US 95/03591

## Box I Observations where certain claims were found unsearchable (Continuation of item 1 of first sheet)

This international search report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons:

1. ☐ Claims Nos.:  
because they relate to subject matter not required to be searched by this Authority, namely:
2. ☐ Claims Nos.:  
because they relate to parts of the international application that do not comply with the prescribed requirements to such an extent that no meaningful international search can be carried out, specifically:
3. ☐ Claims Nos.:  
because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a).

## Box II Observations where unity of invention is lacking (Continuation of item 2 of first sheet)

This International Searching Authority found multiple inventions in this international application, as follows:

SEE ANNEXED SHEET

1. ☐ As all required additional search fees were timely paid by the applicant, this international search report covers all searchable claims.
2. ☐ As all searchable claims could be searched without effort justifying an additional fee, this Authority did not invite payment of any additional fee.
3. ☒ As only some of the required additional search fees were timely paid by the applicant, this international search report covers only those claims for which fees were paid, specifically claims Nos.:  
  
1-32, 33-57, 125, 130, 164-165, 228, 252, 289, 322
4. ☐ No required additional search fees were timely paid by the applicant. Consequently, this international search report is restricted to the invention first mentioned in the claims; it is covered by claims Nos.:

Remark on Protest

- ☐ The additional search fees were accompanied by the applicant's protest.
- ☐ No protest accompanied the payment of additional search fees.

# INTERNATIONAL SEARCH REPORT

INVITATION TO PAY ADDITIONAL FEES

International application No.  
PCT/US 95/03591

1. Claims 1-32: Method of selecting a sequence of graphic symbols (ideographs).
2. Claims 33-57, 125, 130, 164-165, 228, 252, 289, 322: Speech synthesizer and menu selection by sound.
3. Claims 58-121, 128, 154-155, 173-174, 180-221, 224-227, 233-236, 238-251, 253, 292-321, 323-325: Menu selection methods.
4. Claims 122-124, 131, 159-160, 163, 166, 175-176, 222, 281-283, 290-291: Character and word data entry method.
5. Claims 132-153, 177-179: Indicating cursor dwell time at a specified position.
6. Claims 167-172, 275-280: Ordering system.
7. Claims 254-174: Cursor alignment/movement method.
8. Claims 230-231, 237: Method for measuring disabled person's ability to move a limb.
9. Claims 126-127, 156-158, 229-230: Cursor controller.

The special technical feature of the first invention is:  
A method of selecting a sequence of graphic symbols (ideographs).

According to Rule 13 PCT non-unity a priori is detected for inventions 2-9 which deal with the following:

2. Speech synthesizer and menu selection by sound.
3. Menu selection methods.
4. Character and word data entry method.
5. Indicating cursor dwell time at a specified position.
6. Ordering system.
7. Curser alignment/movement method.
8. Method to measure disabled person's ability to move a limb.
9. Cursor controller.
